Camera Calibration

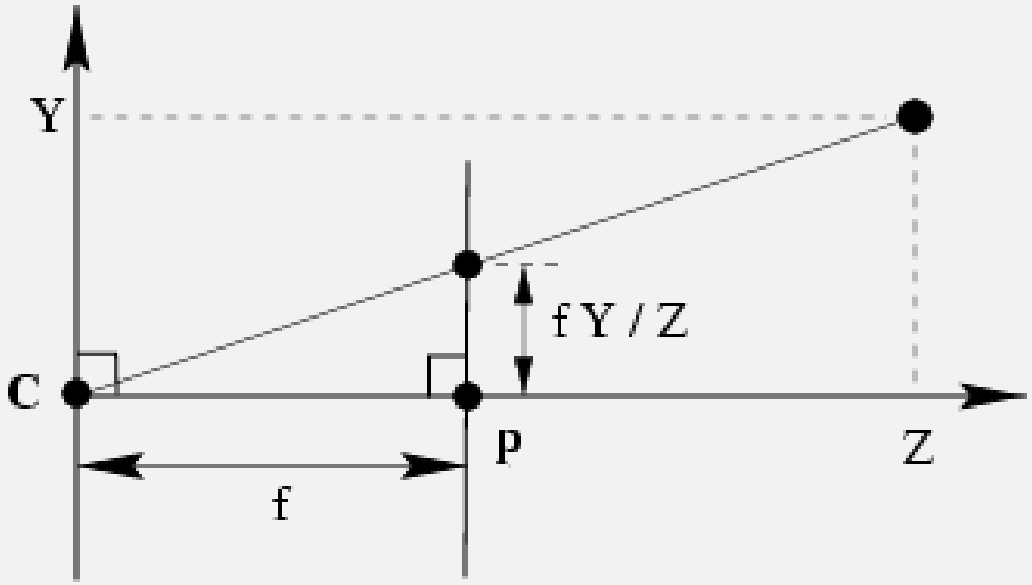
Pinhole Camera Projection Model



$$x = \frac{fX}{Z} \qquad y = \frac{fY}{Z}$$

$$\begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \sim \begin{pmatrix} fX \\ fY \\ Z \end{pmatrix} = \begin{bmatrix} f & 0 & 0 & 0 \\ 0 & f & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

$$\begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \sim \begin{pmatrix} fX \\ fY \\ Z \end{pmatrix} = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

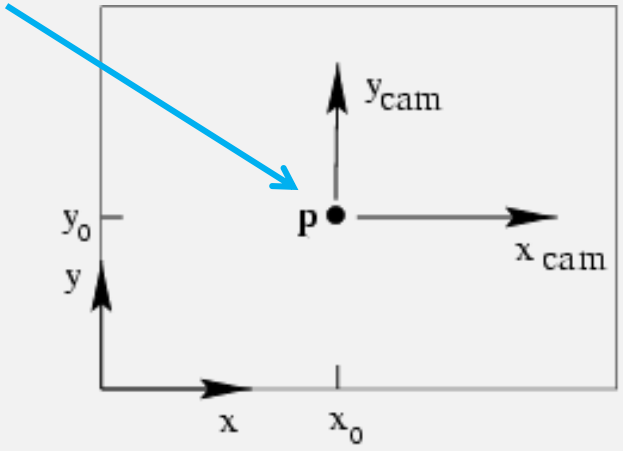
intrinsic matrix

extrinsic matrix (Camera Coordinate =World Coordinate)

$$\mathbf{x} \sim \mathbf{K}[\mathbf{I}|0]\mathbf{X}$$

Principal Point Offset

principal point



$$\begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \sim \begin{pmatrix} fX \\ fY \\ Z \end{pmatrix} = \begin{bmatrix} f & 0 & x_0 \\ 0 & f & y_0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

$$\mathbf{x} \sim \mathbf{K}\left[\mathbf{I}|0\right]\mathbf{X}$$

Intrinsic Matrix

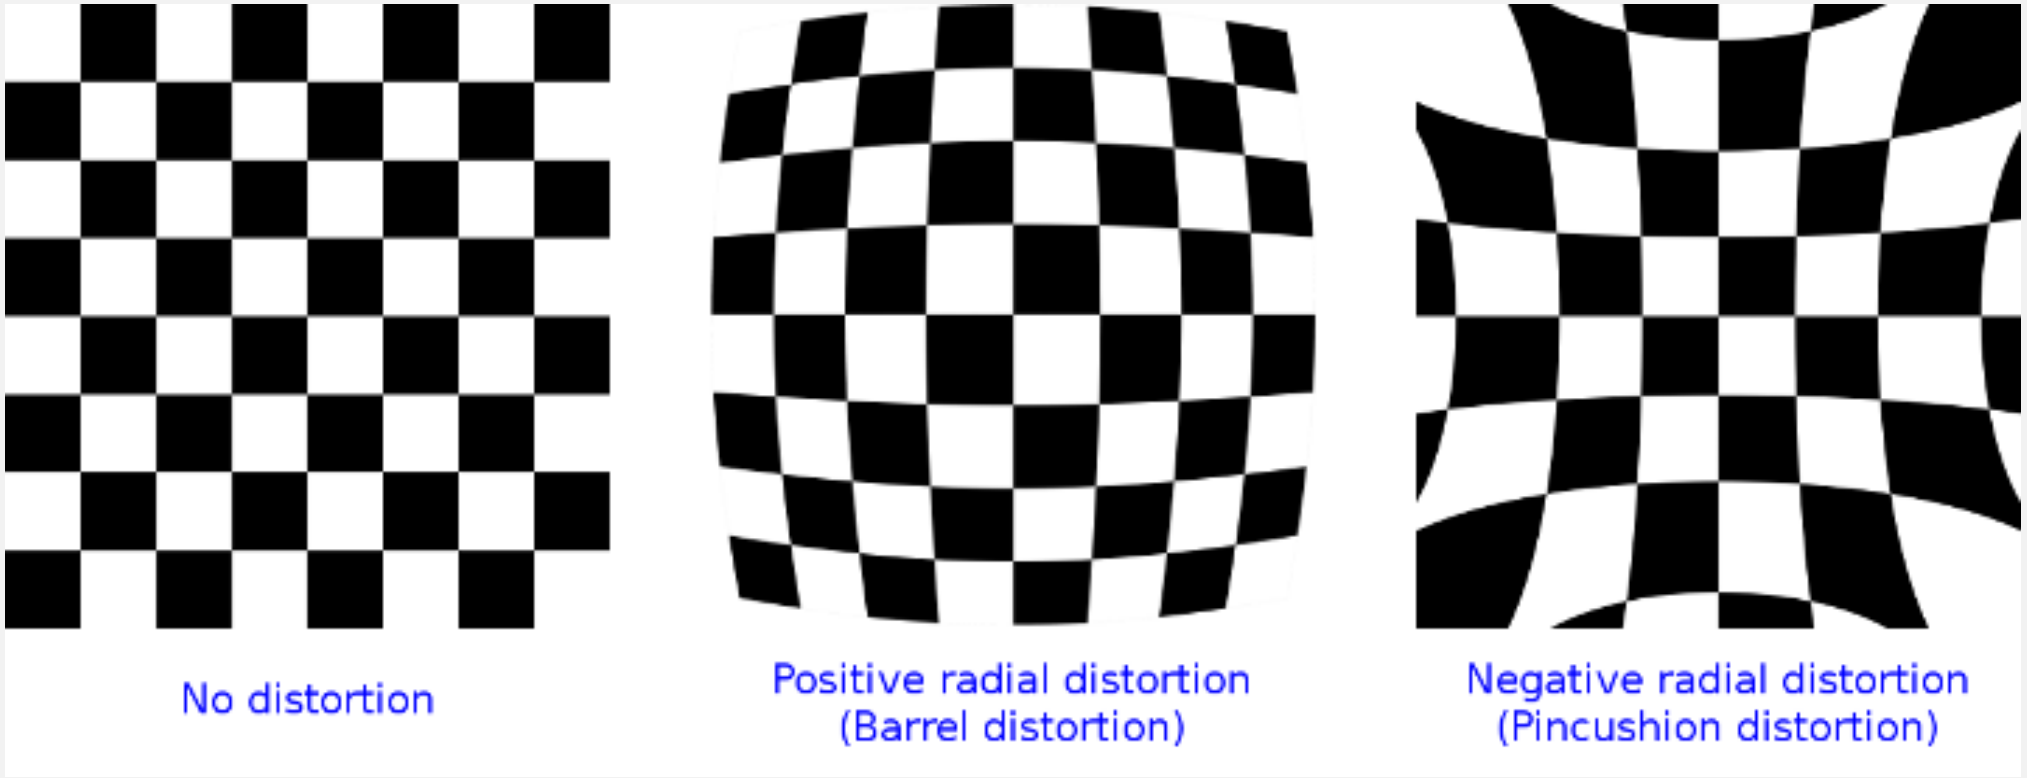
$$\mathbf{K} = \begin{bmatrix} f & 0 & x_0 \\ 0 & f & y_0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\mathbf{K} = \begin{bmatrix} fa & s & x_0 \\ 0 & f & y_0 \\ 0 & 0 & 1 \end{bmatrix}$$

Good enough for modeling the camera projection?

a : aspect ratio (for non-square pixels)
s : skew (for non-rectangular pixels)

Radial Distortion Caused by Imperfect Lens



No distortion

Positive radial distortion
(Barrel distortion)

Negative radial distortion
(Pincushion distortion)

Camera Pose (Camera Rotation and Translation)

$$\begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix} = \mathbf{R}_{3\times3} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} + \mathbf{t}$$

$$\begin{pmatrix} x \\ y \\ 1 \end{pmatrix} \sim \begin{bmatrix} f & 0 & x_0 \\ 0 & f & y_0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \mathbf{R} | \mathbf{t} \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$

$$\mathbf{x} \sim \mathbf{K} \begin{bmatrix} \mathbf{R} | \mathbf{t} \end{bmatrix} \mathbf{X}$$

Camera Calibration Methods

- Two main categories for estimating both intrinsic and extrinsic parameters
  - Photometric calibration
    - Use reference objects with known geometry (Chessboard)
  - Self Calibration
    - Assume static scene and use structure from motion

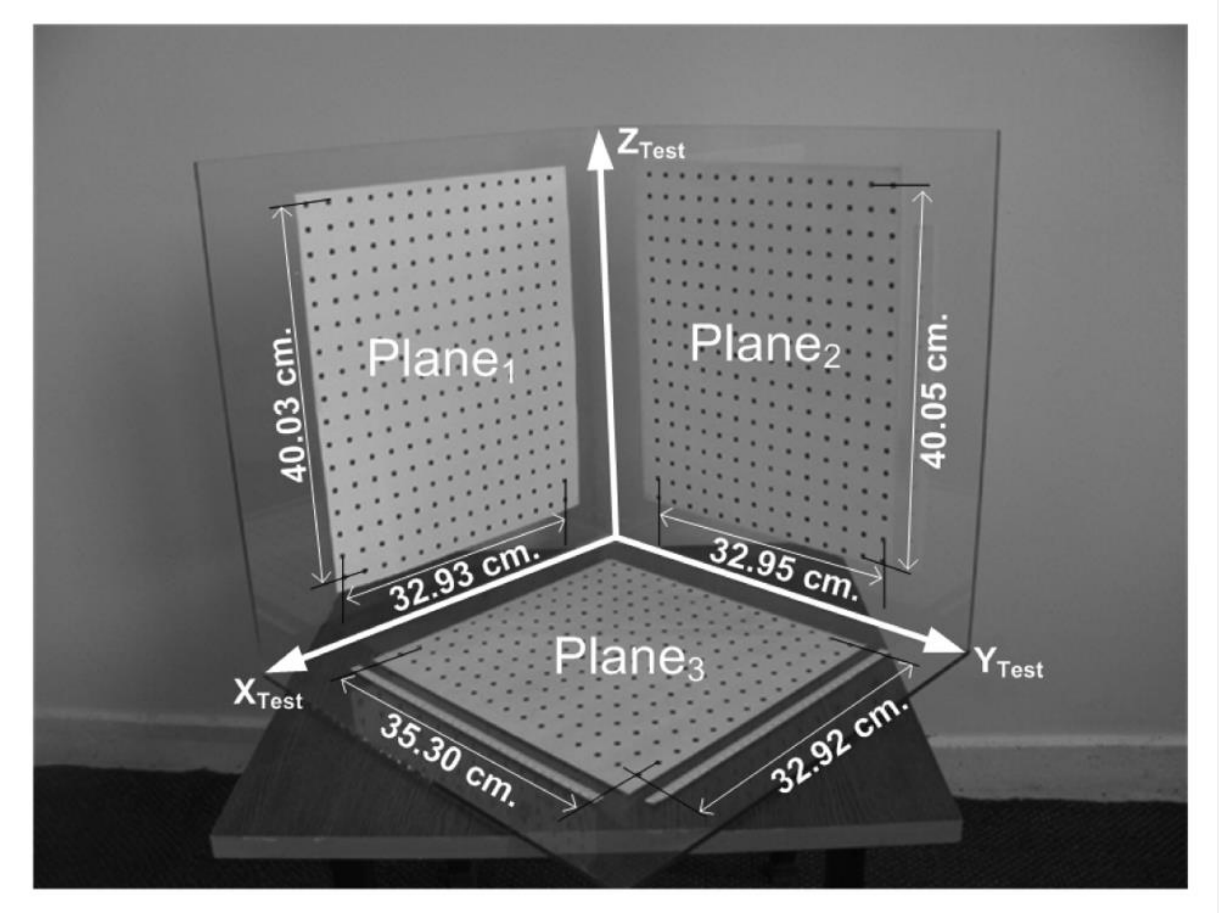
Linear Regression

$$\mathbf{x} \sim \mathbf{K}\left[\mathbf{R}|\mathbf{t}\right]\mathbf{X} = \mathbf{M}\mathbf{X}$$

$$\begin{bmatrix} u \\ v \\ 1 \end{bmatrix} \sim \begin{bmatrix} m_{00} & m_{01} & m_{02} & m_{03} \\ m_{10} & m_{11} & m_{12} & m_{13} \\ m_{20} & m_{21} & m_{22} & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$

- Directly estimate 11 unknowns in the **M** matrix using known 3D points (X_i, Y_i, Z_i) and measured feature positions (u_i, v_i)

Linear Regression (Cont.)



Linear Regression (Cont.)

$$u_i = \frac{m_{00}X_i + m_{01}Y_i + m_{02}Z_i + m_{03}}{m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1}$$

$$v_i = \frac{m_{10}X_i + m_{11}Y_i + m_{12}Z_i + m_{13}}{m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1}$$

$$u_i(m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1) = m_{00}X_i + m_{01}Y_i + m_{02}Z_i + m_{03}$$

$$v_i(m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1) = m_{10}X_i + m_{11}Y_i + m_{12}Z_i + m_{13}$$

Linear Regression (Cont.)

$$u_i(m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1) = m_{00}X_i + m_{01}Y_i + m_{02}Z_i + m_{03}$$

$$v_i(m_{20}X_i + m_{21}Y_i + m_{22}Z_i + 1) = m_{10}X_i + m_{11}Y_i + m_{12}Z_i + m_{13}$$

$$\begin{bmatrix} X_i & Y_i & Z_i & 1 & 0 & 0 & 0 & 0 & -u_iX_i & -u_iY_i & -u_iZ_i & -u_i \\ 0 & 0 & 0 & 0 & X_i & Y_i & Z_i & 1 & -v_iX_i & -v_iY_i & -v_iZ_i & -v_i \end{bmatrix} \begin{bmatrix} m_{00} \\ m_{01} \\ m_{02} \\ m_{03} \\ m_{10} \\ m_{11} \\ m_{12} \\ m_{13} \\ m_{20} \\ m_{21} \\ m_{22} \\ m_{23} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Solve for Projection Matrix M
using least-square techniques

Normal Equation

- Given an overdetermined linear system

$$\mathbf{Ax} = \mathbf{b}$$

- The normal equation is to minimize the sum of square differences between left and right sides

$$\mathbf{A^T Ax} = \mathbf{A^T b}$$

Normal Equation

$$\begin{bmatrix} a_{11} & \dots & a_{1m} \\ \vdots & & \vdots \\ \vdots & & \vdots \\ \vdots & & \vdots \\ a_{n1} & \dots & a_{nm} \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} = \begin{bmatrix} b_1 \\ \vdots \\ \vdots \\ \vdots \\ b_n \end{bmatrix}$$

$$\mathbf{Ax}-\mathbf{b} = \begin{bmatrix} \sum_{j=1}^{m} a_{1j}x_j \\ \vdots \\ \sum_{j=1}^{m} a_{ij}x_j \\ \vdots \\ \sum_{j=1}^{m} a_{nj}x_j \end{bmatrix} - \begin{bmatrix} b_1 \\ \vdots \\ b_i \\ \vdots \\ b_n \end{bmatrix} = \begin{bmatrix} \left(\sum_{j=1}^{m} a_{1j}x_j\right) - b_1 \\ \vdots \\ \left(\sum_{j=1}^{m} a_{ij}x_j\right) - b_i \\ \vdots \\ \left(\sum_{j=1}^{m} a_{nj}x_j\right) - b_n \end{bmatrix}$$

n×*m*, *n* equations, *m* variables

$$E(\mathbf{x}) = \left(\mathbf{Ax}-\mathbf{b}\right)^2 = \sum_{i=1}^{n}\left[\left(\sum_{j=1}^{m} a_{ij}x_j\right) - b_i\right]^2$$

Normal Equation

$$E(\mathbf{x}) = (\mathbf{Ax} - \mathbf{b})^2 = \sum_{i=1}^{n} \left[\left(\sum_{j=1}^{m} a_{ij} x_j \right) - b_i \right]^2$$

$$0 = \frac{\partial E}{\partial x_1} = \sum_{i=1}^{n} 2 \left[\left(\sum_{j=1}^{m} a_{ij} x_j \right) - b_i \right] a_{i1}$$

$$= 2 \sum_{i=1}^{n} a_{i1} \sum_{j=1}^{m} a_{ij} x_j - 2 \sum_{i=1}^{n} a_{i1} b_i$$

$$0 = \frac{\partial E}{\partial \mathbf{x}} = 2(\mathbf{A}^{\mathbf{T}}\mathbf{Ax} - \mathbf{A}^{\mathbf{T}}\mathbf{b}) \rightarrow \mathbf{A}^{\mathbf{T}}\mathbf{Ax} = \mathbf{A}^{\mathbf{T}}\mathbf{b}$$

Normal Equation

$$
\begin{aligned}
&\left(\mathbf{Ax}-\mathbf{b}\right)^2 \\
&=\left(\mathbf{Ax}-\mathbf{b}\right)^T\left(\mathbf{Ax}-\mathbf{b}\right) \\
&=\left(\left(\mathbf{Ax}\right)^T-\mathbf{b}^T\right)\left(\mathbf{Ax}-\mathbf{b}\right) \\
&=\left(\mathbf{x}^\mathbf{T}\mathbf{A}^\mathbf{T}-\mathbf{b}^\mathbf{T}\right)\left(\mathbf{Ax}-\mathbf{b}\right) \\
&=\mathbf{x}^\mathbf{T}\mathbf{A}^\mathbf{T}\mathbf{Ax}-\mathbf{b}^\mathbf{T}\mathbf{Ax}-\mathbf{x}^\mathbf{T}\mathbf{A}^\mathbf{T}\mathbf{b}+\mathbf{b}^\mathbf{T}\mathbf{b} \\
&=\mathbf{x}^\mathbf{T}\mathbf{A}^\mathbf{T}\mathbf{Ax}-\left(\mathbf{A}^\mathbf{T}\mathbf{b}\right)^\mathbf{T}\mathbf{x}-\left(\mathbf{A}^\mathbf{T}\mathbf{b}\right)^\mathbf{T}\mathbf{x}+\mathbf{b}^\mathbf{T}\mathbf{b}
\end{aligned}
$$

$$
\Rightarrow \frac{\partial E}{\partial \mathbf{x}}=2\mathbf{A}^\mathbf{T}\mathbf{Ax}-2\mathbf{A}^\mathbf{T}\mathbf{b}
$$

Linear Regression

- Advantages:
  - All parameters of the camera are summarized in one matrix
  - Given any world point, it is easy to predict the corresponding position in the image
- Disadvantages:
  - Intrinsic and extrinsic parameters can not be derived separately
  - More unknowns than true degrees of freedom

Non-Linear Optimization

- A probabilistic view of least square
- Feature measurement equations

$$u_i = f(\mathbf{M}, \mathbf{x}_i) + n_i = \hat{u}_i + n_i, \quad n_i \sim N(0, \sigma)$$
$$v_i = g(\mathbf{M}, \mathbf{x}_i) + m_i = \hat{v}_i + m_i, \quad m_i \sim N(0, \sigma)$$

- Probability of $\mathbf{M}$ given $\{(u_i, v_i)\}$:

$$P = \prod_i p(u_i|\hat{u}_i)p(v_i|\hat{v}_i)$$
$$= \prod_i e^{-(u_i-\hat{u}_i)^2/\sigma^2} e^{-(v_i-\hat{v}_i)^2/\sigma^2}$$

Optimal Estimation

- Likelihood of **M** given $\{(u_i, v_i)\}$:

$$L = -\log P = \sum_i (u_i - \hat{u}_i)^2/\sigma_i^2 + (v_i - \hat{v}_i)^2/\sigma_i^2$$

- Minimize L

How ?

Optimal Estimation

- Non-linear regression (least squares), because the relations between $\hat{u}_i$ and u_i are non-linear functions of $\mathbf{M}$

$$\mathbf{u} - \hat{\mathbf{u}} \sim \mathbf{u} - \mathbf{K}\left[\mathbf{R}|\mathbf{t}\right]\mathbf{X}$$

known constant

- Use Levenberg-Marquardt method to minimize the least square error

Least Square Fitting

Least Squares Problem

Find $\mathbf{x}^*$, a local minimizer for

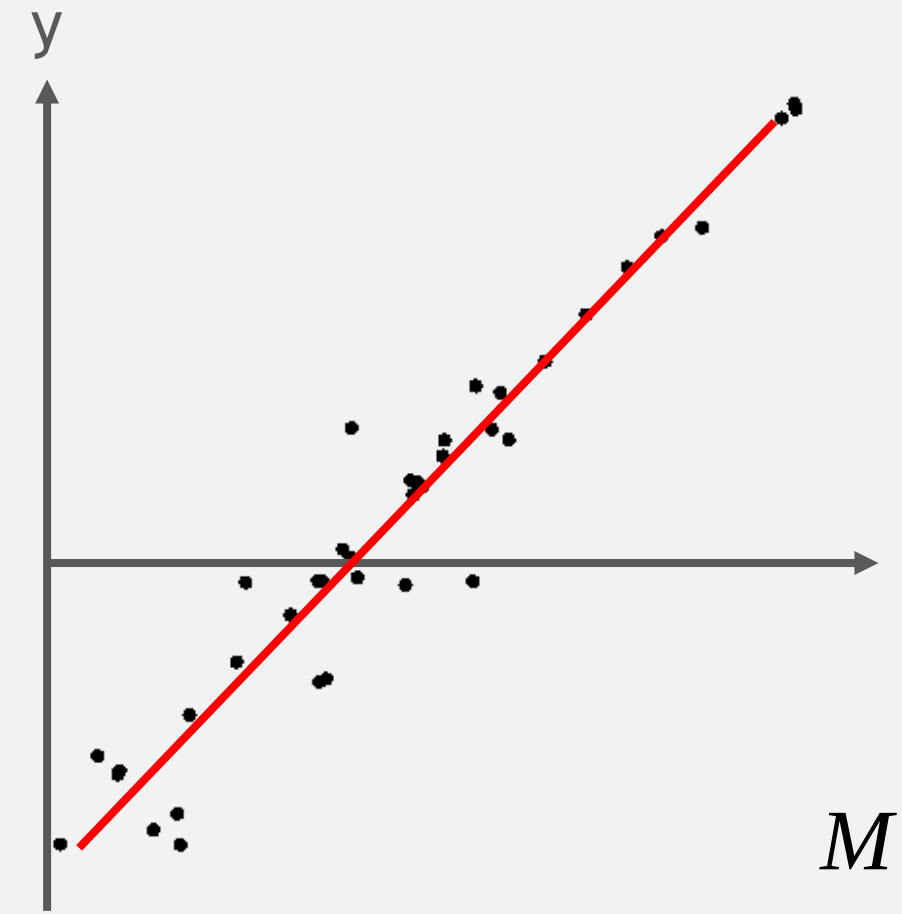
$$F(\mathbf{x}) = \frac{1}{2}\sum_{i=1}^{m}(f_i(\mathbf{x}))^2 \ ,$$

where $f_i : \mathbb{R}^n \mapsto \mathbb{R}$, $i = 1, \ldots, m$ are given functions, and $m \geq n$.

m: number of data points

n: number of parameters

Linear Least Square Fitting



model parameters

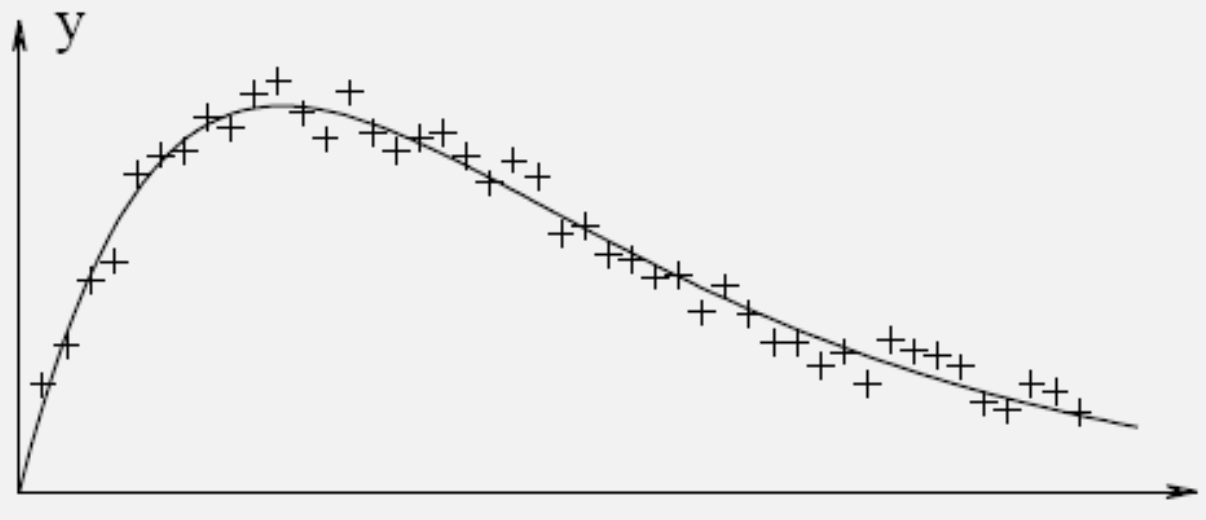
$$y(t) = M(t;\mathbf{x}) = x_0 + x_1 t$$

$$f_i(x) = y_i - M(t_i;\mathbf{x})$$

residual prediction

$M(t;\mathbf{x}) = x_0 + x_1 t + x_2 t^3$ is linear, too.

Nonlinear Least Square Fitting



model $M(t;\mathbf{x}) = x_3 e^{x_1 t} + x_4 e^{x_2 t}$

parameters $\mathbf{x} = [x_1, x_2, x_3, x_4]^T$

residuals $f_i(\mathbf{x}) = y_i - M(t_i;\mathbf{x})$

$= y_i - \left(x_3 e^{x_1 t} + x_4 e^{x_2 t}\right)$

Function Minimization

Least square is related to function minimization.

Global Minimizer

Given $F : \mathbb{R}^n \mapsto \mathbb{R}$. Find

$$\mathbf{x}^+ = \operatorname{argmin}_{\mathbf{x}} \{F(\mathbf{x})\} .$$

It is very hard to solve in general.
Here, we only consider a simpler problem of finding local minimum.

Local Minimizer

Given $F : \mathbb{R}^n \mapsto \mathbb{R}$. Find $\mathbf{x}^*$ so that

$$F(\mathbf{x}^*) \leq F(\mathbf{x}) \quad \text{for} \quad \|\mathbf{x} - \mathbf{x}^*\| < \delta .$$

Function Minimization

We assume that the cost function F is differentiable and so smooth that the following *Taylor expansion* is valid,[2)]

$$F(\mathbf{x}+\mathbf{h}) \;=\; F(\mathbf{x}) + \mathbf{h}^\top \mathbf{g} + \tfrac{1}{2}\mathbf{h}^\top \mathbf{H}\,\mathbf{h} + O(\|\mathbf{h}\|^3)\;,$$

where $\mathbf{g}$ is the *gradient*,

$$\mathbf{g} \;\equiv\; \mathbf{F}'(\mathbf{x}) \;=\; \begin{bmatrix} \dfrac{\partial F}{\partial x_1}(\mathbf{x}) \\ \vdots \\ \dfrac{\partial F}{\partial x_n}(\mathbf{x}) \end{bmatrix},$$

and $\mathbf{H}$ is the *Hessian*,

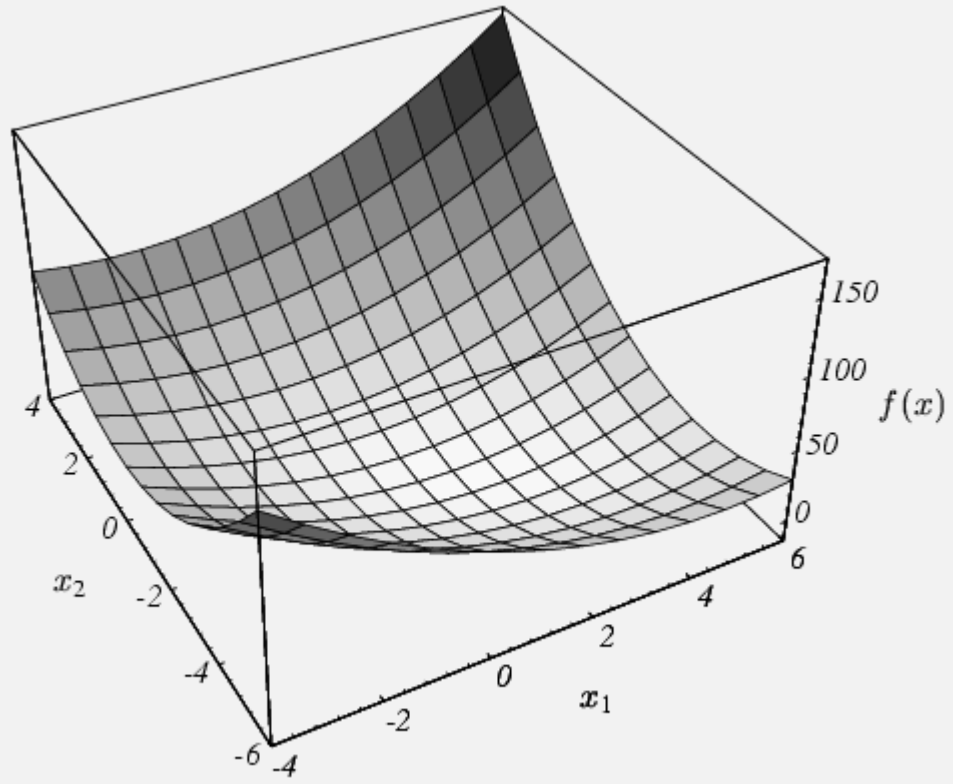
$$\mathbf{H} \;\equiv\; \mathbf{F}''(\mathbf{x}) \;=\; \left[\frac{\partial^2 F}{\partial x_i \partial x_j}(\mathbf{x})\right] .$$

Quadratic Functions

Approximate the function with
a quadratic function within
a small neighborhood

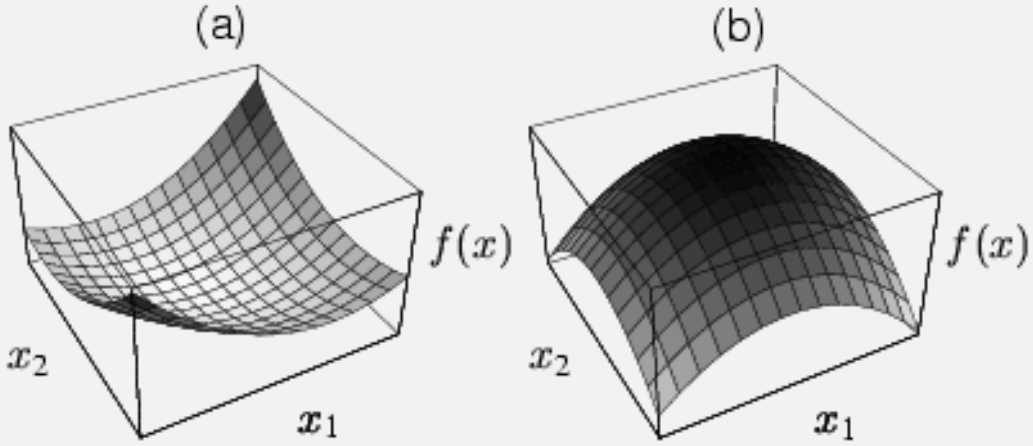
$$f(x) = \frac{1}{2}x^T Ax - b^T x + c$$

$$A = \begin{bmatrix} 3 & 2 \\ 2 & 6 \end{bmatrix}, \qquad b = \begin{bmatrix} 2 \\ -8 \end{bmatrix}, \qquad c = 0.$$



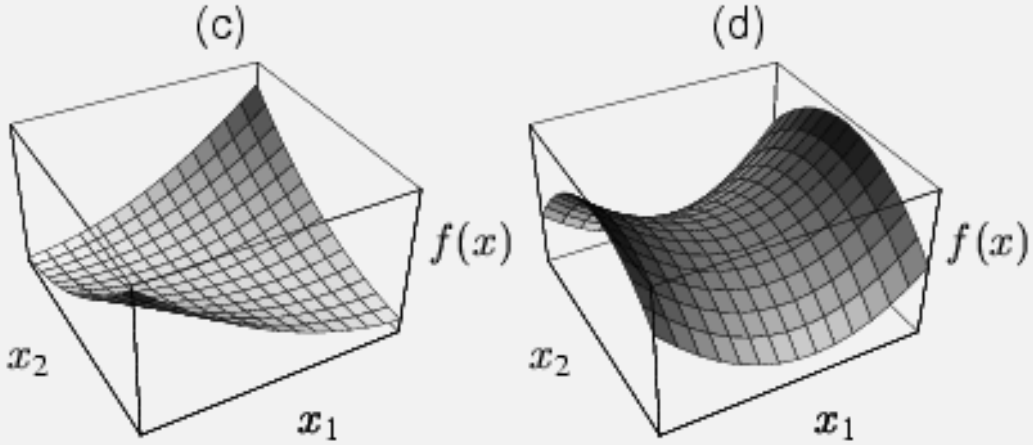
Quadratic Functions

A is positive definite.
All eigenvalues are positive.
For all x, $x^T Ax>0$.



A is negative definite.
All eigenvalues are negative.
For all x, $x^T Ax<0$.

A is singular



A is indefinite

Function Minimization

Theorem 1.5. Necessary condition for a local minimizer.
If x^* is a local minimizer, then

$$g^* \equiv F'(x^*) = 0 .$$

Why?

By definition, if $\mathbf{x}^*$ is a local minimizer,

$$\|\mathbf{h}\| \text{ is small enough} \longrightarrow \mathbf{F(x^* + h) > F(x^*)}$$

$$\mathbf{F(x^* + h) = F(x^*) + h^T F'(x^*) + O(\|h\|^2)}$$

Function Minimization

Theorem 1.5. Necessary condition for a local minimizer.
If $\mathbf{x}^*$ is a local minimizer, then

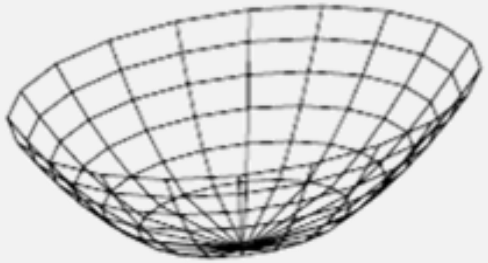
$$\mathbf{g}^* \equiv \mathbf{F}'(\mathbf{x}^*) = \mathbf{0}\,.$$

Definition 1.6. Stationary point. If

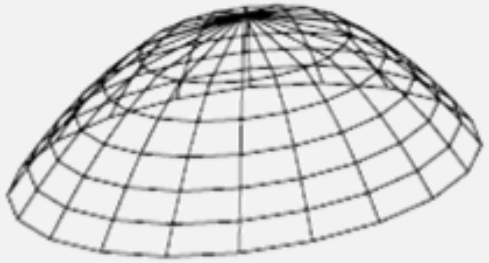
$$\mathbf{g}_s \equiv \mathbf{F}'(\mathbf{x}_s) = \mathbf{0}\,,$$

then $\mathbf{x}_s$ is said to be a *stationary point* for F.

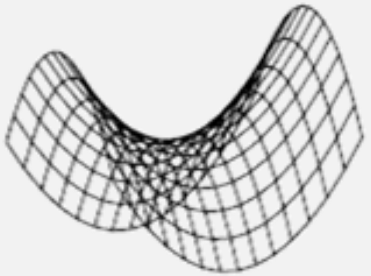
$$F(\mathbf{x}_s+\mathbf{h}) = F(\mathbf{x}_s) + \tfrac{1}{2}\mathbf{h}^\top \mathbf{H}_s\,\mathbf{h} + O(\|\mathbf{h}\|^3)$$



a) minimum



b) maximum



c) saddle point

Function Minimization

Theorem 1.8. Sufficient condition for a local minimizer.
Assume that $\mathbf{x}_s$ is a stationary point and that $\mathbf{F}''(\mathbf{x}_s)$ is positive definite.
Then $\mathbf{x}_s$ is a local minimizer.

$$F(\mathbf{x}_s+\mathbf{h}) = F(\mathbf{x}_s) + \tfrac{1}{2}\mathbf{h}^\top \mathbf{H}_s\, \mathbf{h} + O(\|\mathbf{h}\|^3)$$

$$\text{with } \mathbf{H}_s = \mathbf{F}''(\mathbf{x}_s)$$

If we request that $\mathbf{H}_s$ is *positive definite*, then its eigenvalues are greater than some number $\delta > 0$

$$\mathbf{h}^\top \mathbf{H}_s\, \mathbf{h} > \delta\, \|\mathbf{h}\|^2$$

Descent Methods

$\mathbf{x}_0, \mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_k \rightarrow \mathbf{x}^* \quad \text{for} \quad k \rightarrow \infty$

1. Find a descent direction $\mathbf{h}_d$
2. find a step length giving a good decrease in the F-value.

Algorithm Descent method

begin

$k := 0$; $\mathbf{x} := \mathbf{x}_0$; *found* := **false** {Starting point}

while (**not** *found*) **and** ($k < k_{max}$)

$\mathbf{h}_d$:= search_direction($\mathbf{x}$) {From $\mathbf{x}$ and downhill}

if (no such $\mathbf{h}$ exists)

found := **true** {$\mathbf{x}$ is stationary}

else

α := step_length($\mathbf{x}, \mathbf{h}_d$) {from $\mathbf{x}$ in direction $\mathbf{h}_d$}

$\mathbf{x} := \mathbf{x} + \alpha\mathbf{h}_d$; $k := k+1$ {next iterate}

end

Descent Direction

$$F(\mathbf{x}+\alpha\mathbf{h}) = F(\mathbf{x}) + \alpha\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) + O(\alpha^2)$$
$$\simeq F(\mathbf{x}) + \alpha\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) \quad \text{for } \alpha \text{ sufficiently small.}$$

Definition: Descent direction.

$\mathbf{h}$ is a descent direction for F at $\mathbf{x}$ if $\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) < 0$.

Steepest Descent Method

$$F(\mathbf{x}+\alpha\mathbf{h}) = F(\mathbf{x}) + \alpha\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) + O(\alpha^2)$$
$$\simeq F(\mathbf{x}) + \alpha\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) \quad \text{for } \alpha \text{ sufficiently small.}$$

$$\boxed{\frac{F(\mathbf{x}) - F(\mathbf{x}+\alpha\mathbf{h})}{\alpha\|\mathbf{h}\|}} = -\frac{1}{\|\mathbf{h}\|}\mathbf{h}^\top\mathbf{F}'(\mathbf{x}) = -\|\mathbf{F}'(\mathbf{x})\|\cos\theta$$

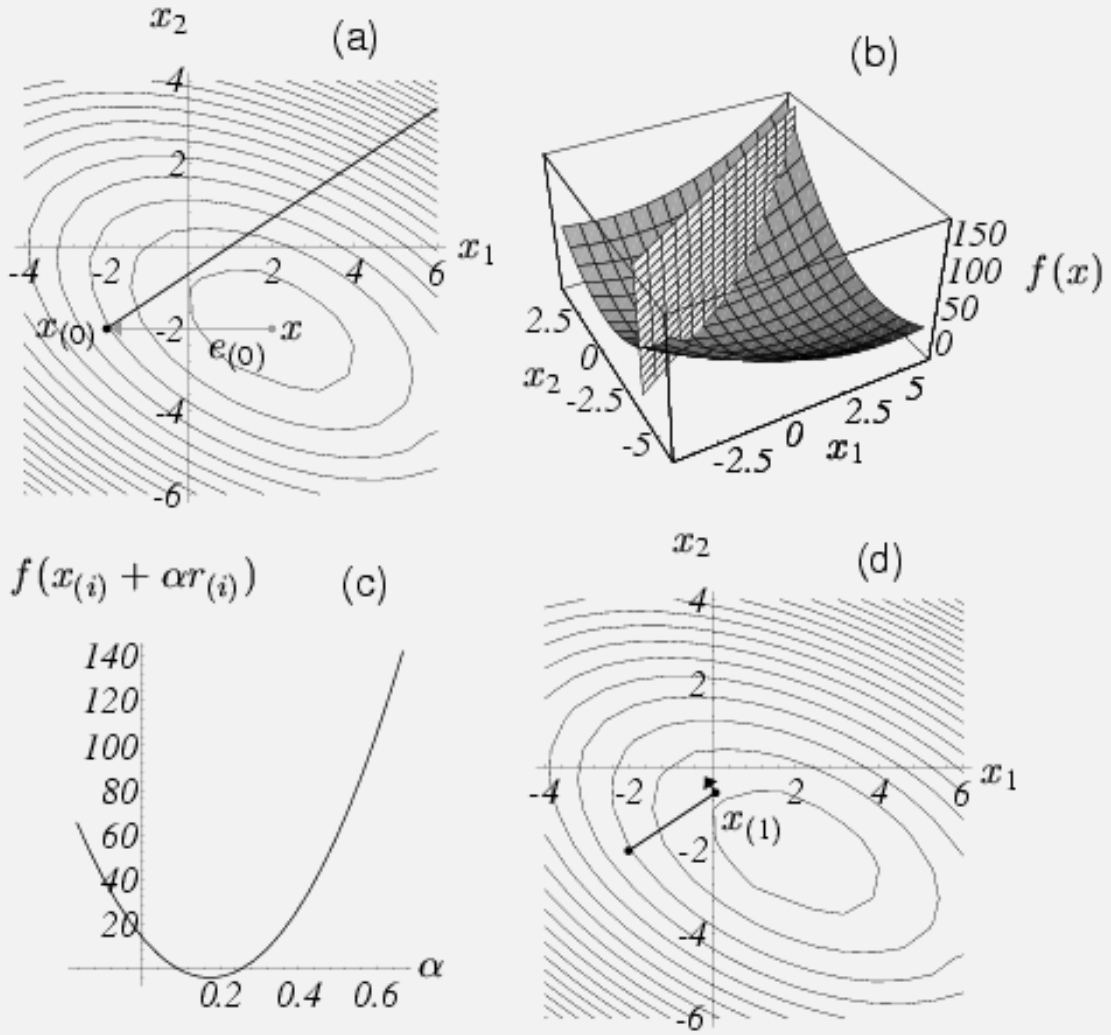
the decrease of ***F(x)*** per unit along h direction

$$\text{greatest gain rate if } \theta = \pi \quad \longrightarrow \quad \mathbf{h}_{sd} = -\mathbf{F}'(\mathbf{x})$$

h_{sd} is a descent direction because $h^T_{sd}\, F'(x) = -F'(x)^2 < 0$

Line Search

$\varphi(\alpha) = F(\mathbf{x}+\alpha\mathbf{h})$, $\mathbf{x}$ and $\mathbf{h}$ fixed, $\alpha \geq 0$.



Find α so that

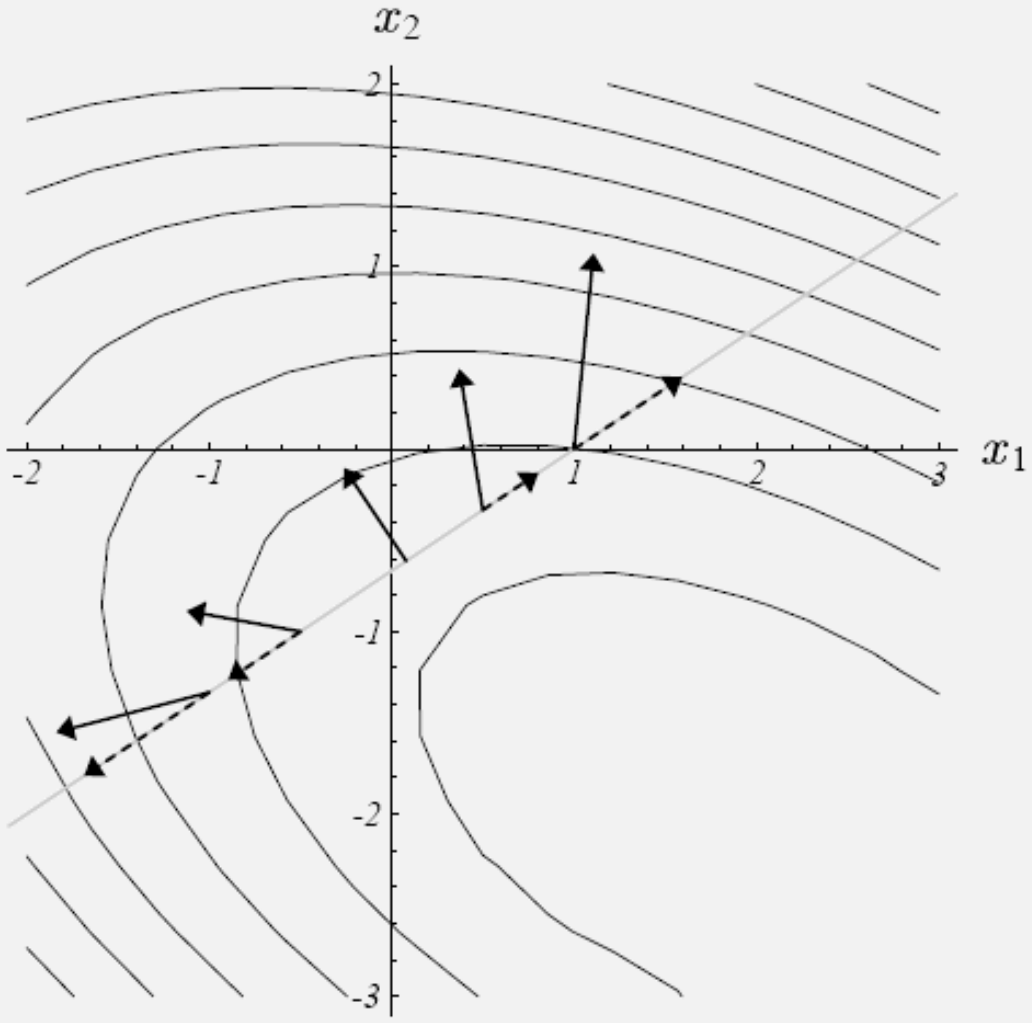
$\varphi(\alpha) = \mathbf{F}(\mathbf{x}_0 + \alpha\mathbf{h})$ is minimum

$$0 = \frac{\partial \varphi(\alpha)}{\partial \alpha} = \frac{\partial \mathbf{F}(\mathbf{x}_0 + \alpha\mathbf{h})}{\partial \alpha}$$

$$= \frac{\partial \mathbf{F}}{\partial \mathbf{x}} \frac{\partial \mathbf{x}}{\partial \alpha} = \mathbf{h}^{\mathrm{T}} \mathbf{F}'(\mathbf{x}_0 + \alpha\mathbf{h})$$

$$\mathbf{h} = -\mathbf{F}'(\mathbf{x}_0)$$

Line Search



$$\mathbf{h}^{\mathrm{T}}\mathbf{F}'(\mathbf{x}_0+\alpha\mathbf{h})=0$$

$$\mathbf{h}=-\mathbf{F}'(\mathbf{x}_0)$$

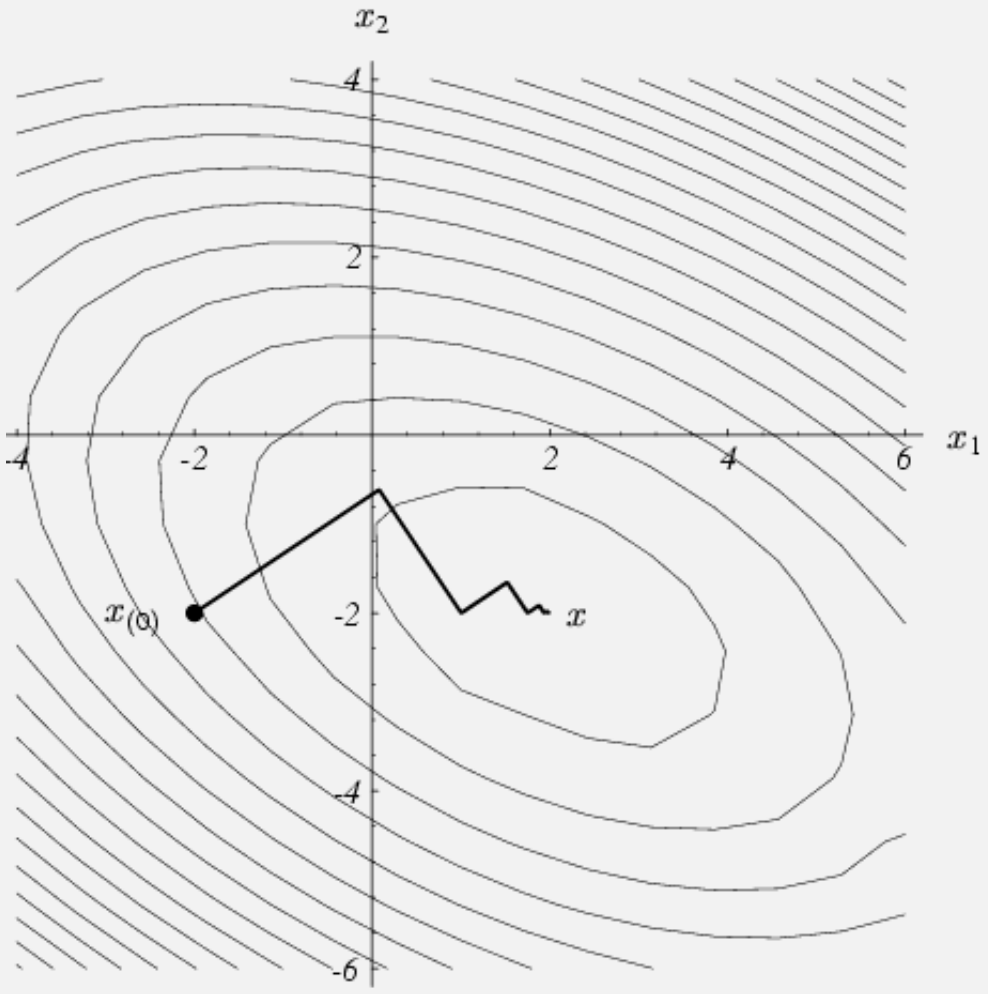
$$\mathbf{h}^{\mathrm{T}}\mathbf{F}'(\mathbf{x}_0+\alpha\mathbf{h})$$

$$=\mathbf{h}^{\mathrm{T}}\left(\mathbf{F}'(\mathbf{x}_0)+\alpha\mathbf{F}''(\mathbf{x}_0)^{\mathrm{T}}\mathbf{h}\right)$$

$$=-\mathbf{h}^{\mathrm{T}}\mathbf{h}+\alpha\mathbf{h}^{\mathrm{T}}\mathbf{H}\mathbf{h}=0$$

$$\alpha=\frac{\mathbf{h}^{\mathrm{T}}\mathbf{h}}{\mathbf{h}^{\mathrm{T}}\mathbf{H}\mathbf{h}}$$

Steepest Descent Method

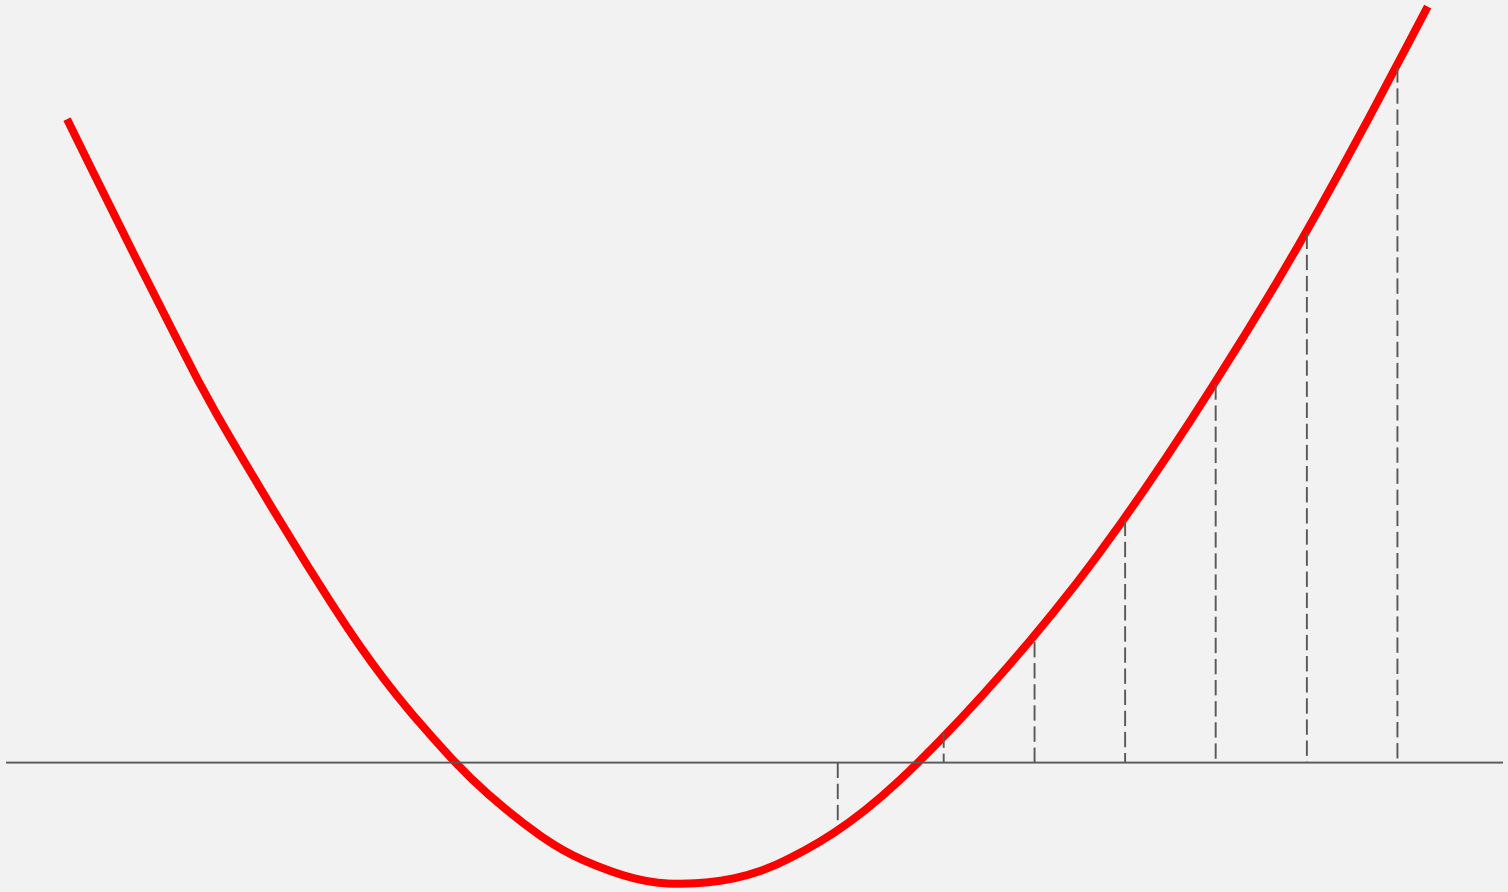


It has good performance in the initial stages of the iterative process.

Converge very slow with a linear rate.

Newton's Method

- Root finding for $f(x)=0$
- March x and test signs
- Determine Δx
  (small→slow; large→ miss)



Newton's Method

- Root finding for *f(x)=0*

Taylor's expansion:

$$f(x_0+\varepsilon) = f(x_0) + f'(x_0)\varepsilon + \frac{1}{2} f''(x_0)\varepsilon^2 + \dots$$

$$0 = \quad f(x_0+\varepsilon) \approx f(x_0) + f'(x_0)\varepsilon$$

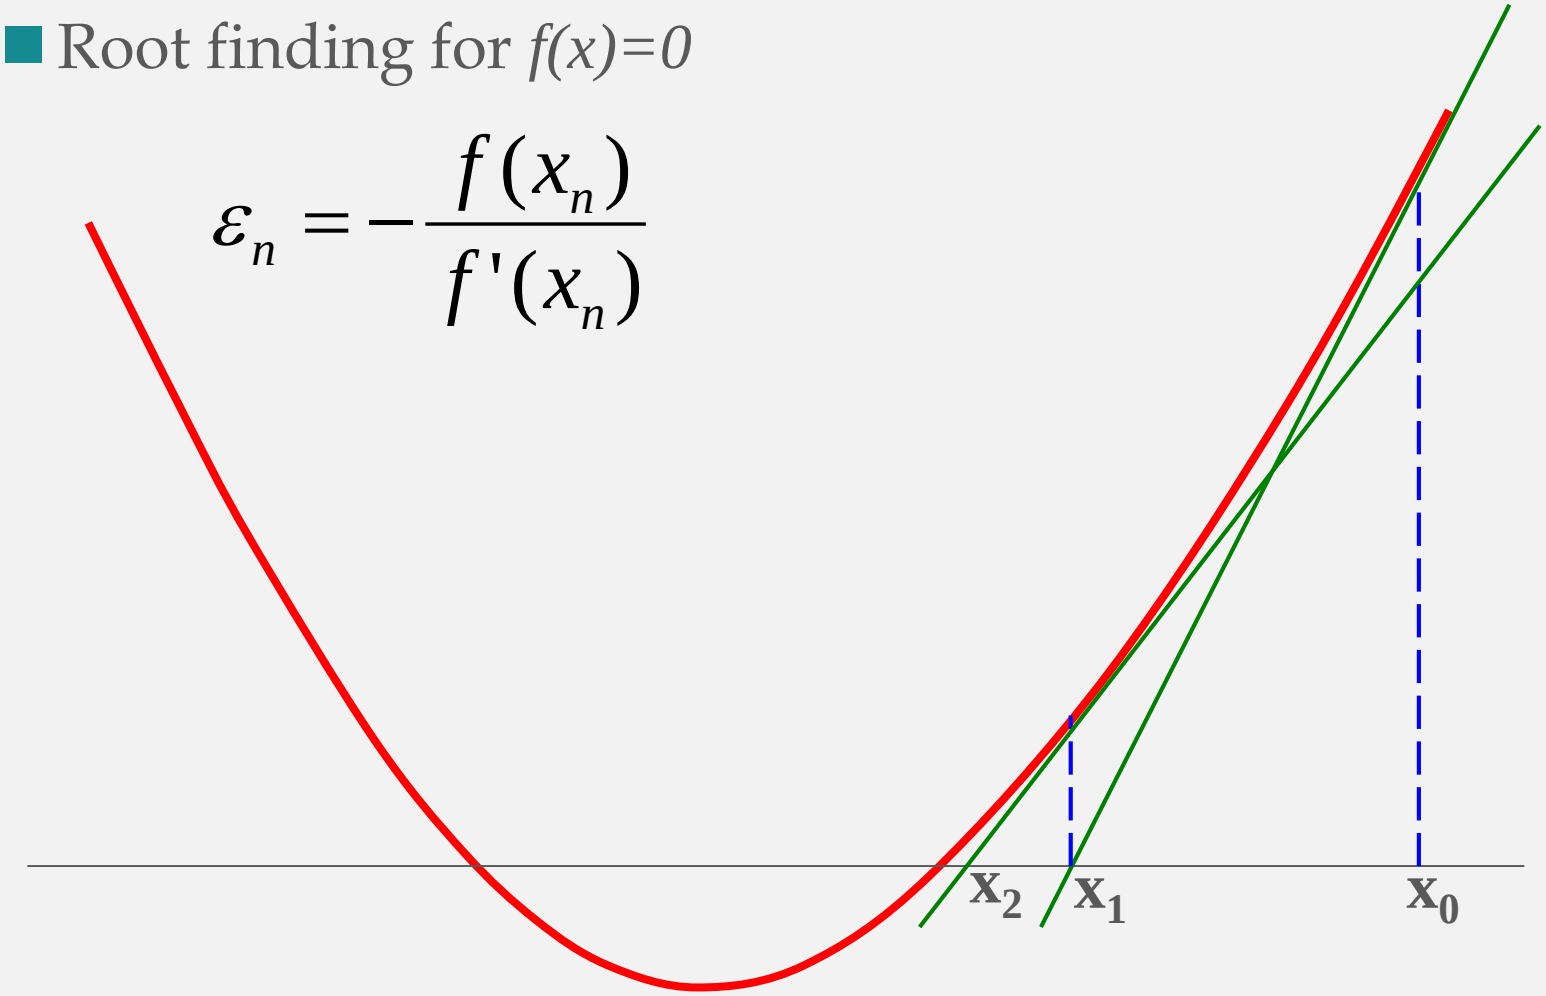
$$\varepsilon = -\frac{f(x_0)}{f'(x_0)}$$

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

Newton's Method

- Root finding for *f(x)=0*

$$\varepsilon_n = -\frac{f(x_n)}{f'(x_n)}$$



Newton's Method

$\mathbf{x}^*$ is a stationary point $\longrightarrow$ it satisfies $\mathbf{F}'(\mathbf{x}^*) = \mathbf{0}$.

$$\begin{aligned}\mathbf{F}'(\mathbf{x}+\mathbf{h}) &= \mathbf{F}'(\mathbf{x}) + \mathbf{F}''(\mathbf{x})\mathbf{h} + O(\|\mathbf{h}\|^2) \\ &\simeq \mathbf{F}'(\mathbf{x}) + \mathbf{F}''(\mathbf{x})\mathbf{h} \quad \text{for } \|\mathbf{h}\| \text{ sufficiently small} \\ &= 0\end{aligned}$$

$$\longrightarrow \mathbf{H}\,\mathbf{h}_n = -\mathbf{F}'(\mathbf{x}) \quad \text{with } \mathbf{H} = \mathbf{F}''(\mathbf{x})$$

$$\mathbf{x} := \mathbf{x} + \mathbf{h}_n$$

Suppose that $\mathbf{H}$ is positive definite

$\longrightarrow \mathbf{u}^\top \mathbf{H}\,\mathbf{u} > 0$ for all nonzero $\mathbf{u}$.

$\longrightarrow 0 < \mathbf{h}_n^\top \mathbf{H}\,\mathbf{h}_n = -\mathbf{h}_n^\top \mathbf{F}'(\mathbf{x})$

$\longrightarrow \mathbf{h}_n$ is a descent direction

Newton's Method

$$\mathbf{h} = -\mathbf{H}^{-1}\mathbf{g}$$

- It requires solving a linear system and H is not always positive definite.
- It has good performance in the final stage of the iterative process, where x is close to x*.

Gauss-Newton Method

- H is not always positive definite
  - ➔ Use the approximate Hessian

$$\mathbf{H} \approx \mathbf{J}^{\mathbf{T}}\mathbf{J}$$

  - No need for second derivative
  - H is positive semi-definite

Hybrid Method

$$
\begin{aligned}
&\textbf{if } \mathbf{F}''(\mathbf{x}) \text{ is positive definite} \\
&\quad \mathbf{h} := \mathbf{h}_{\mathrm{n}} \\
&\textbf{else} \\
&\quad \mathbf{h} := \mathbf{h}_{\mathrm{sd}} \\
&\mathbf{x} := \mathbf{x} + \alpha \mathbf{h}
\end{aligned}
$$

This needs to calculate second-order derivative which might not be available.

Levenberg-Marquardt Method

- LM can be thought of as a combination of steepest descent and the Newton method.
  - When the current solution is far from the correct one, the algorithm behaves like a steepest descent method: slow, but guaranteed to converge.
  - When the current solution is close to the correct solution, it becomes a Newton's method.

Jacobian matrix

- The Jacobian matrix is the matrix of all first-order partial derivatives of a vector-valued function. $F : \mathbf{R}^n \to \mathbf{R}^m$

$$F(x_1, x_2, \ldots x_n)$$
$$= (f_1(x_1, x_2, \ldots x_n), f_2(x_1, x_2, \ldots x_n), \ldots f_m(x_1, x_2, \ldots x_n))$$

$$J_F(x_1, x_2, \ldots x_n) \quad \text{or} \quad \frac{\partial(f_1, f_2, \ldots f_m)}{\partial(x_1, x_2, \ldots x_n)} = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \cdots & \frac{\partial f_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial f_m}{\partial x_1} & \cdots & \frac{\partial f_m}{\partial x_n} \end{bmatrix}$$

$$F(\mathbf{x} + \Delta\mathbf{x}) \approx F(\mathbf{x}) + J_F(\mathbf{x})\Delta\mathbf{x}$$

Levenberg-Marquardt Method

Given a set of measurements $\mathbf{x}$, try to find the best parameter vector $\mathbf{p}$ so that the squared distance $\varepsilon^T \varepsilon$ is minimal.

Here, $\varepsilon = \mathbf{x} - \hat{\mathbf{x}}$, with $\hat{\mathbf{x}} = f(\mathbf{p})$.

For a small $||\delta_\mathbf{p}||$, $f(\mathbf{p} + \delta_\mathbf{p}) \approx f(\mathbf{p}) + \mathbf{J}\delta_\mathbf{p}$

$\mathbf{J}$ is the Jacobian matrix $\frac{\partial f(\mathbf{p})}{\partial \mathbf{p}}$

it is required to find the $\delta_\mathbf{p}$ that minimizes the quantity

$$||\mathbf{x} - f(\mathbf{p} + \delta_\mathbf{p})|| \approx ||\mathbf{x} - f(\mathbf{p}) - \mathbf{J}\delta_\mathbf{p}|| = ||\epsilon - \mathbf{J}\delta_\mathbf{p}||$$

$$\mathbf{J}^T\mathbf{J}\delta_\mathbf{p} = \mathbf{J}^T\epsilon$$

$$\mathbf{N}\delta_\mathbf{p} = \mathbf{J}^T\epsilon$$

damping term

$$\mathbf{N}_{ii} = \mu + \left[\mathbf{J}^T\mathbf{J}\right]_{ii}$$

Levenberg-Marquardt Method

$$(\mathbf{J}^{\mathbf{T}}\mathbf{J} + \mu\mathbf{I})\mathbf{h} = -\mathbf{g}$$

- μ=0 → Newton's method
- μ→∞ → steepest descent method

- Strategy for choosing μ
  - Start with some small μ
  - If F is not reduced, keep trying larger μ until it does
  - If F is reduced, accept it and reduce μ for the next iteration

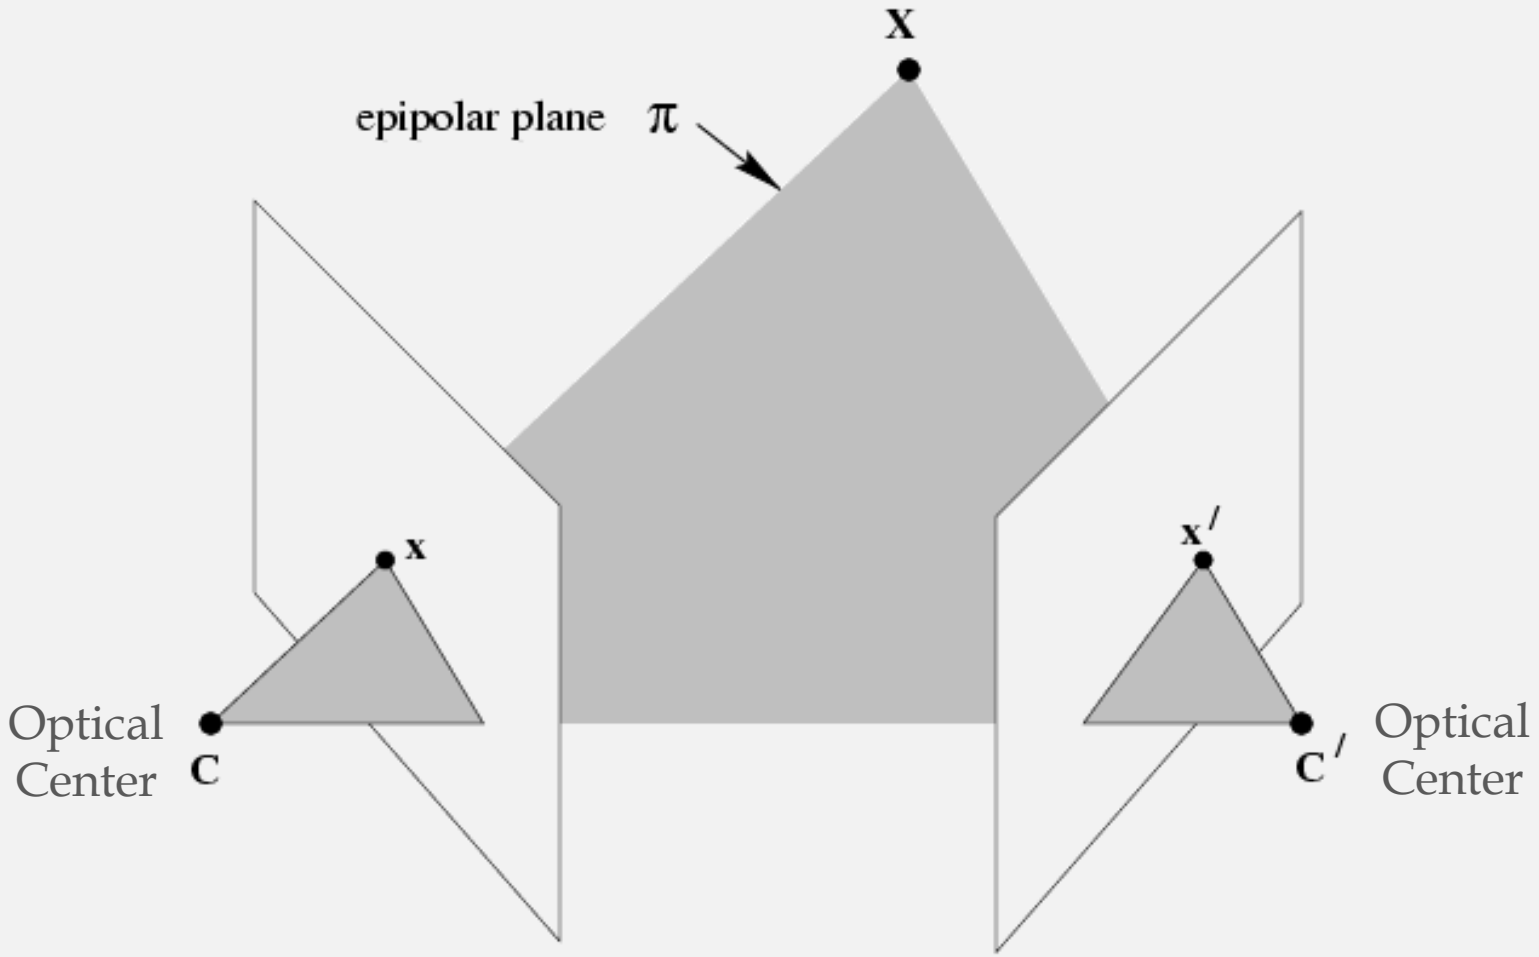
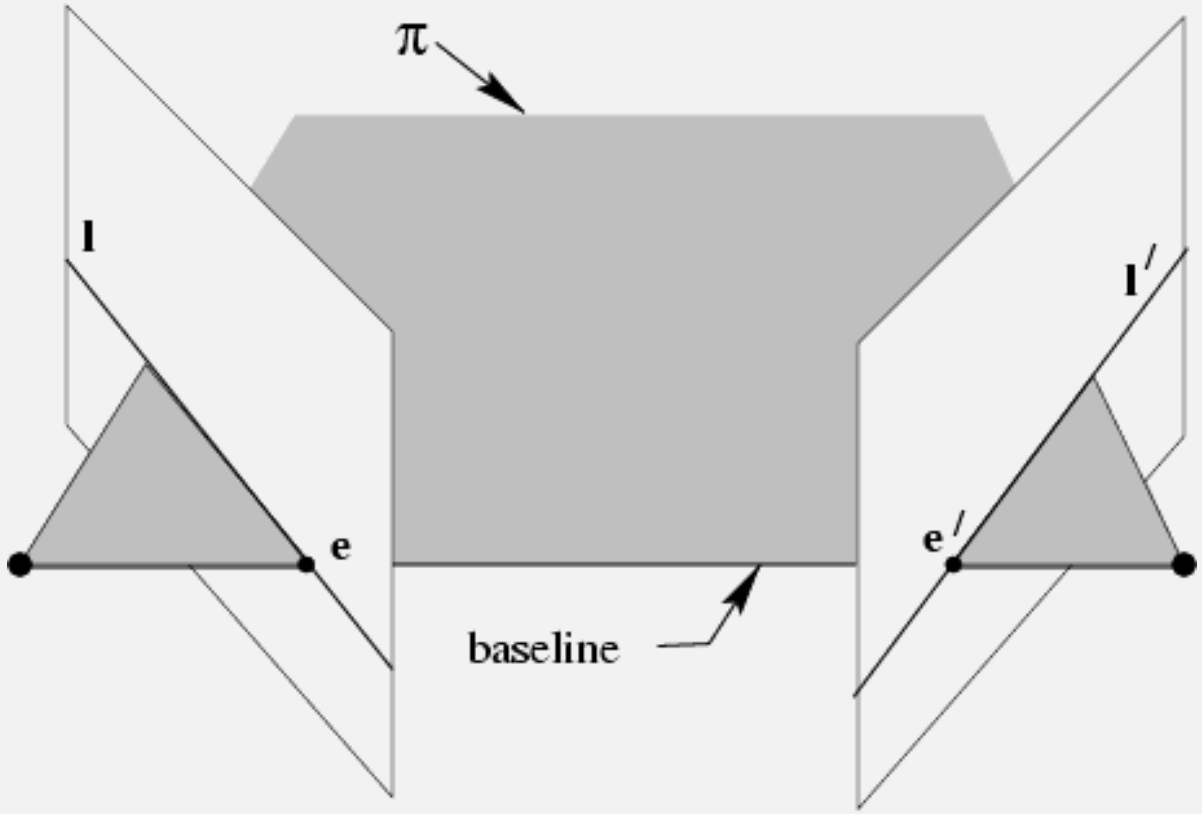
Epipolar geometry & Fundamental Matrix



C,C′,x,x′ and X are coplanar

Epipolar Geometry



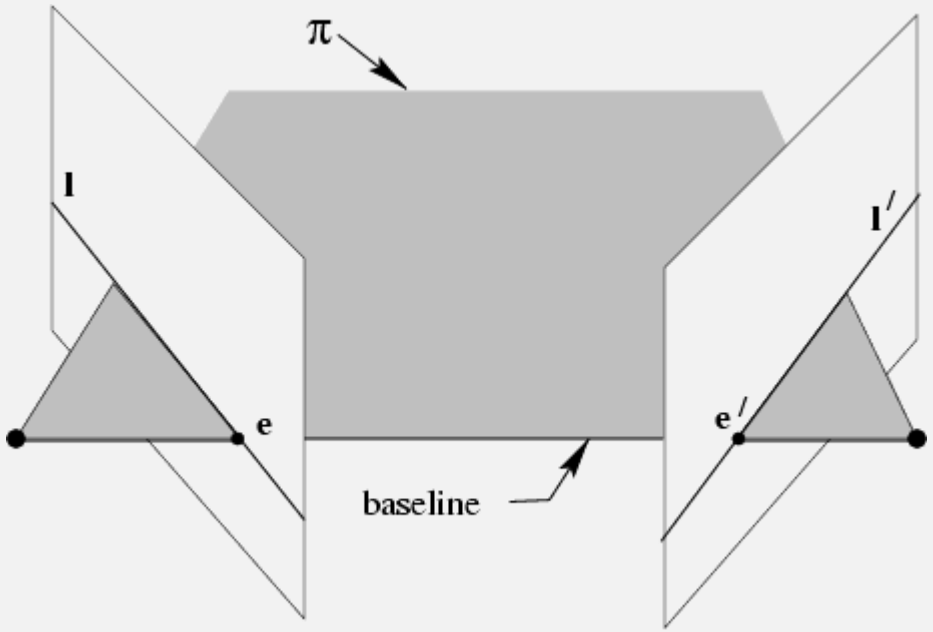
All points on π project on l and l′

Epipolar Geometry

epipolar pole

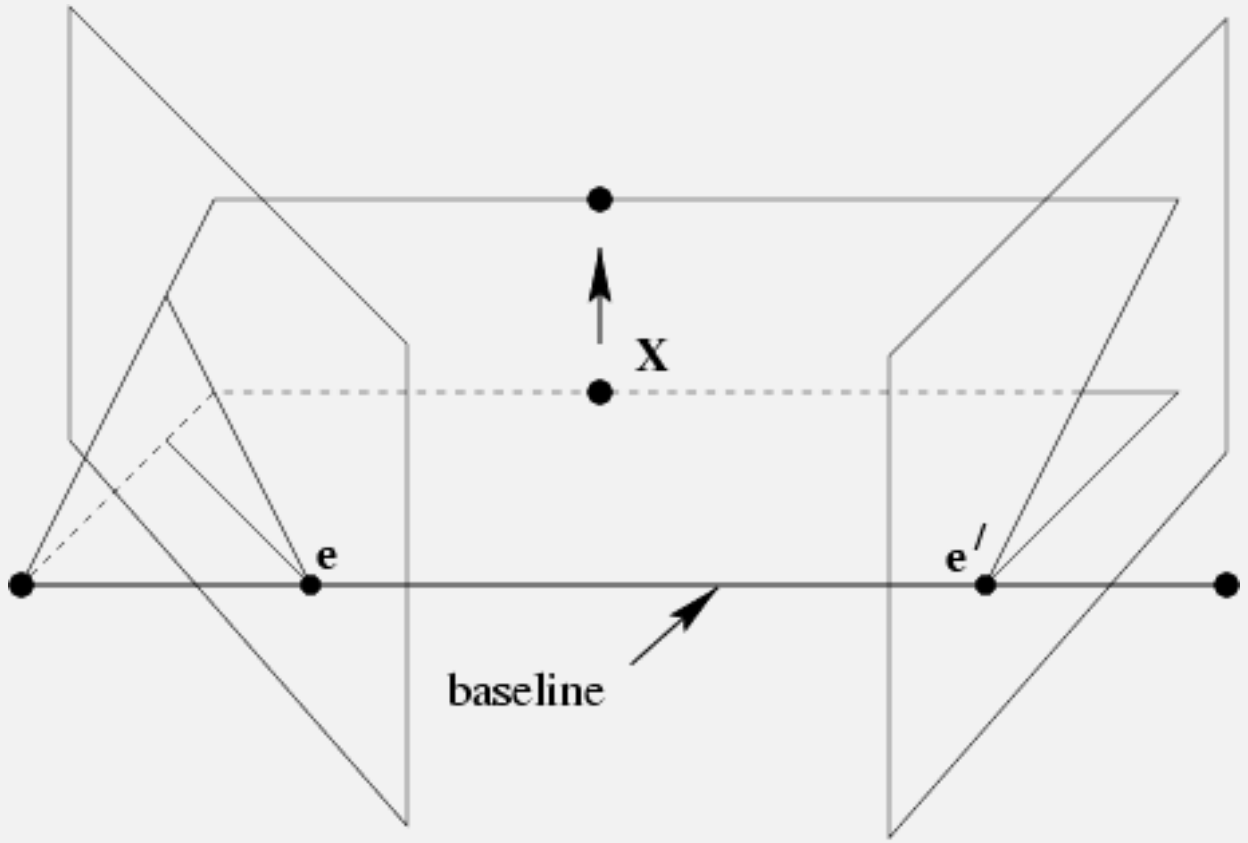
= intersection of baseline with image plane

= projection of projection center in other image



epipolar plane = plane containing baseline
epipolar line = intersection of epipolar plane with image

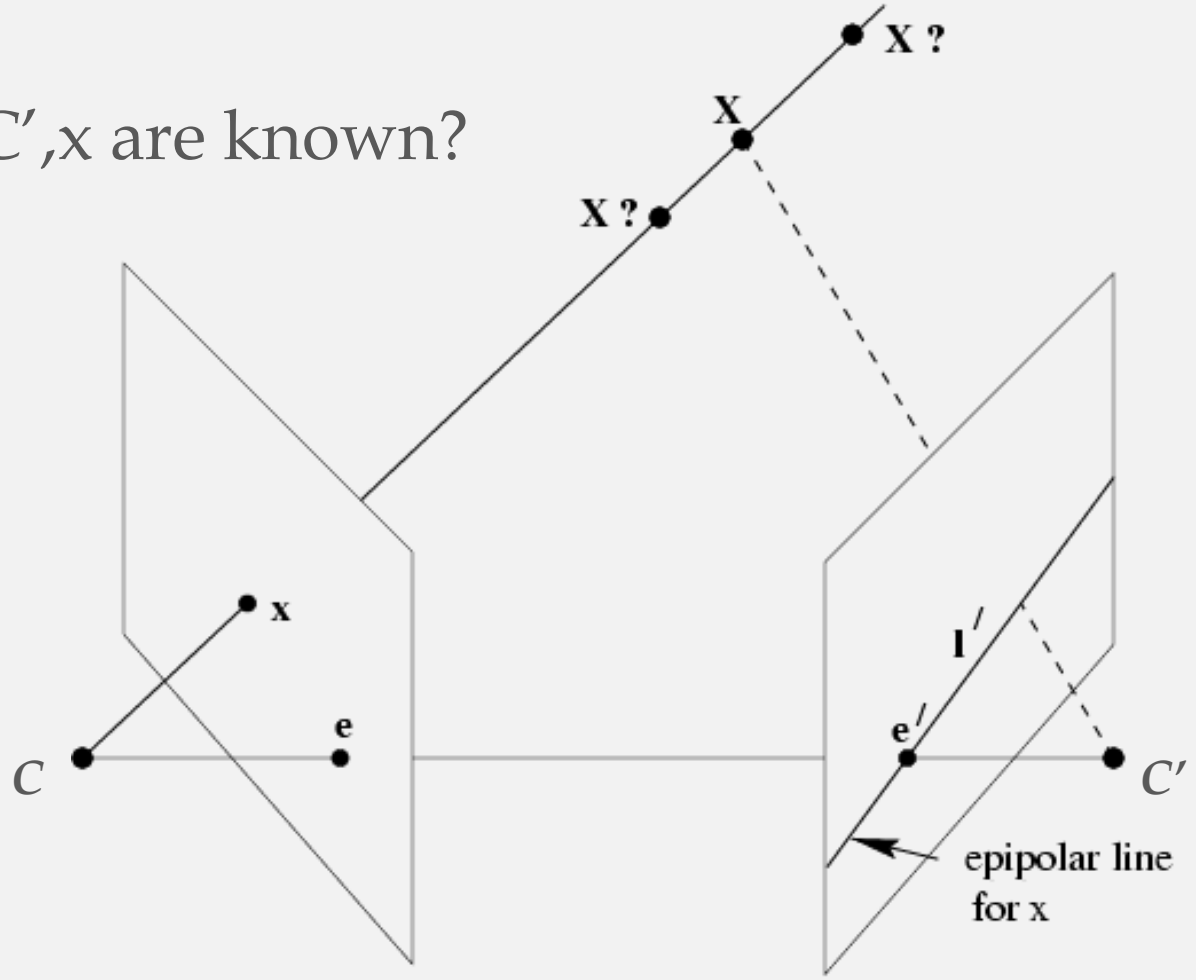
Epipolar Geometry



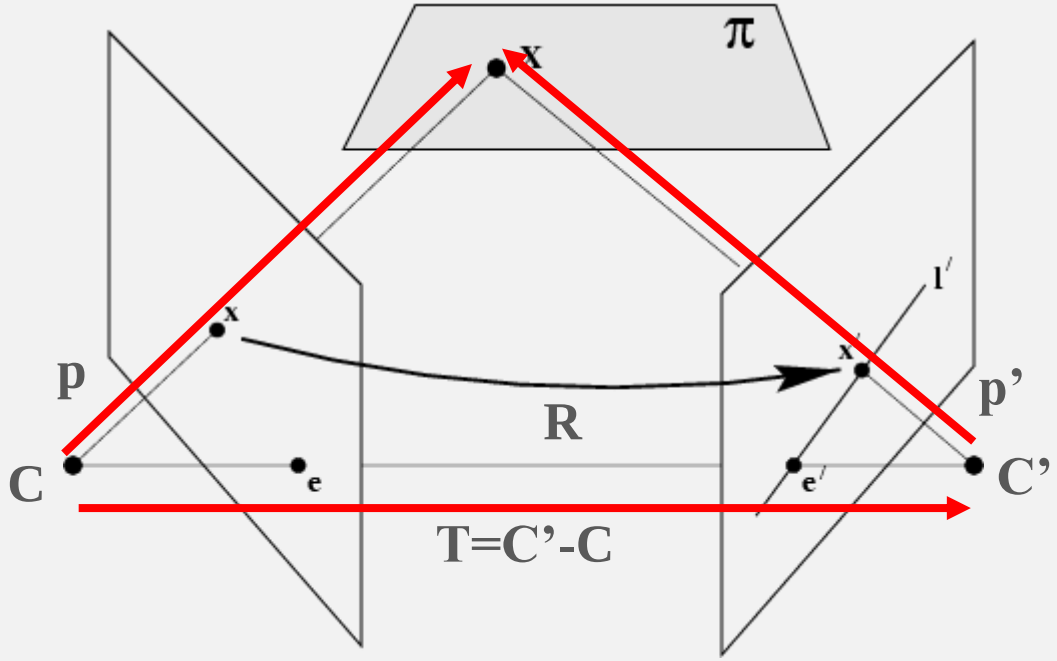
Family of planes π and lines *l* and *l'* intersect at *e* and *e'*

Epipolar Geometry

What if only C,C′,x are known?



Fundamental Matrix F



Two reference frames are related via the extrinsic parameters

$$\mathbf{p} = \mathbf{R}\mathbf{p}' + \mathbf{T}$$

Fundamental Matrix F

$$\mathbf{p} = \mathbf{R}\mathbf{p}' + \mathbf{T}$$

Multiply both sides by $\mathbf{p}^T [\mathbf{T}]_\times$

$$[\mathbf{T}]_\times = \begin{bmatrix} 0 & -T_z & T_y \\ T_z & 0 & -T_x \\ -T_y & T_x & 0 \end{bmatrix}$$

$$\mathbf{p}^T [\mathbf{T}]_\times \mathbf{p} = \mathbf{p}^T [\mathbf{T}]_\times (\mathbf{R}\mathbf{p}' + \mathbf{T})$$

$$\Rightarrow \quad 0 = \mathbf{p}^T [\mathbf{T}]_\times \mathbf{R}\mathbf{p}'$$

$$\Rightarrow \quad \mathbf{p}^T \mathbf{E} \mathbf{p}' = 0$$

essential matrix

Fundamental Matrix F

$$\mathbf{p}^{T}\mathbf{E}\mathbf{p}' = 0$$

Let $\mathbf{M}$ and $\mathbf{M}'$ be the intrinsic matrices, then

$$\mathbf{p} = \mathbf{M}^{-1}\mathbf{x} \qquad \mathbf{p}' = \mathbf{M}'^{-1}\mathbf{x}'$$

$$\Rightarrow \quad (\mathbf{M}^{-1}\mathbf{x})^{T}\mathbf{E}(\mathbf{M}'^{-1}\mathbf{x}') = 0$$

$$\Rightarrow \quad \mathbf{x}^{T}\boxed{\mathbf{M}^{-T}\mathbf{E}\mathbf{M}'^{-1}}\mathbf{x}' = 0$$

$$\Rightarrow \quad \mathbf{x}^{T}\boxed{\mathbf{F}}\mathbf{x}' = 0$$

fundamental matrix

Fundamental Matrix F

- The fundamental matrix is the algebraic representation of epipolar geometry

- The fundamental matrix satisfies the condition that for any pair of corresponding points $x \leftrightarrow x'$ in the two images

$$x^T F x' = 0 \qquad \left(x^T l = 0\right)$$

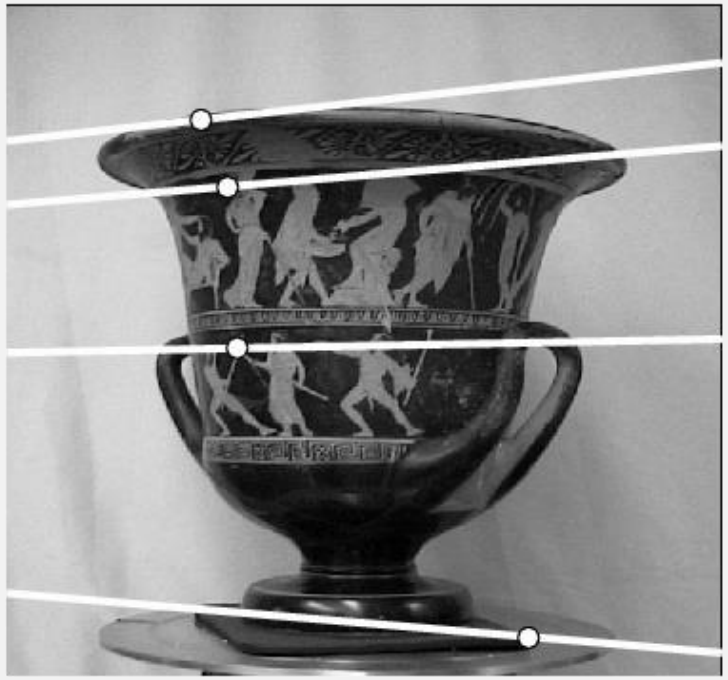
Fundamental Matrix F

- F is the unique 3x3 rank 2 matrix that satisfies $x^T F x' = 0$ for all $x \leftrightarrow x'$

1. Transpose: if F is fundamental matrix for (P,P'), then F^T is fundamental matrix for (P',P)
2. Epipolar lines: $l = Fx'$ & $l' = F^T x$
3. Epipoles: on all epipolar lines, thus $e^T F x' = 0$, $\forall x' \Rightarrow e^T F = 0$, similarly $Fe' = 0$
4. F has 7 d.o.f. , i.e. 3x3-1(homogeneous)-1(rank2)
5. F is a correlation, projective mapping from a point x to a line $l = Fx'$ (not a proper correlation, i.e. not invertible)

Fundamental Matrix F

- It can be used for
  - Simplifies matching
  - Allows to detect wrong matches



Estimation of F : 8-point algorithm

- The fundamental matrix F is defined by

$$\mathbf{x}^{\mathrm{T}}\mathbf{F}\mathbf{x}'=0$$

for any pair of matches x and x′ in two images.

- Let x=$(u,v,1)^{\mathrm{T}}$ and x′=$(u',v',1)^{\mathrm{T}}$, $\mathbf{F}=\begin{bmatrix} f_{11} & f_{12} & f_{13} \\ f_{21} & f_{22} & f_{23} \\ f_{31} & f_{32} & f_{33} \end{bmatrix}$

each match gives a linear equation :

$$uu'f_{11}+uv'f_{12}+uf_{13}+vu'f_{21}+vv'f_{22}+vf_{23}+u'f_{31}+v'f_{32}+f_{33}=0$$

Estimation of F : 8-point algorithm

$$\begin{bmatrix} u_1u_1' & u_1v_1' & u_1 & v_1u_1' & v_1v_1' & v_1 & u_1' & v_1' & 1 \\ u_2u_2' & u_2v_2' & u_2 & v_2u_2' & v_2v_2' & v_2 & u_2' & v_2' & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ u_nu_n' & u_nv_n' & u_n & v_nu_n' & v_nv_n' & v_n & u_n' & v_n' & 1 \end{bmatrix} \begin{bmatrix} f_{11} \\ f_{12} \\ f_{13} \\ f_{21} \\ f_{22} \\ f_{23} \\ f_{31} \\ f_{32} \\ f_{33} \end{bmatrix} = 0$$

- In reality, instead of solving $\mathbf{Af} = 0$, we seek $\mathbf{f}$ to minimize $\|\mathbf{Af}\|$ subj. $\|\mathbf{f}\| = 1$. Find the vector corresponding to the least singular value.

Estimation of F : 8-point algorithm

- To enforce that F is of rank 2, F is replaced by F′ that minimizes $\|\mathbf{F}-\mathbf{F}'\|$ subject to $\det \mathbf{F}' = 0$.
- It is achieved by SVD. Let $\mathbf{F} = \mathbf{U}\Sigma\mathbf{V}^{\mathrm{T}}$, where

$$\Sigma = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & \sigma_3 \end{bmatrix}, \text{ let } \Sigma' = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

then $\mathbf{F}' = \mathbf{U}\Sigma'\mathbf{V}^{\mathrm{T}}$ is the solution.

Estimation of F : 8-point algorithm

```
% Build the constraint matrix
   A = [x2(1,:)‘.*x1(1,:)'   x2(1,:)'.*x1(2,:)'  x2(1,:)' ...
        x2(2,:)'.*x1(1,:)'   x2(2,:)'.*x1(2,:)'  x2(2,:)' ...
        x1(1,:)'             x1(2,:)'            ones(npts,1) ];
   [U,D,V] = svd(A);
% Extract fundamental matrix from the column of V
% corresponding to the smallest singular value.
   F = reshape(V(:,9),3,3)';
% Enforce rank2 constraint
   [U,D,V] = svd(F);
   F = U*diag([D(1,1) D(2,2) 0])*V';
```

Estimation of F : 8-point algorithm

- Pros: it is linear, easy to implement and fast
- Cons: susceptible to noise

Problem with 8-point algorithm

$$\begin{bmatrix} u_1u_1' & u_1v_1' & u_1 & v_1u_1' & v_1v_1' & v_1 & u_1' & v_1' & 1 \\ u_2u_2' & u_2v_2' & u_2 & v_2u_2' & v_2v_2' & v_2 & u_2' & v_2' & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ u_nu_n' & u_nv_n' & u_n & v_nu_n' & v_nv_n' & v_n & u_n' & v_n' & 1 \end{bmatrix} \begin{bmatrix} f_{11} \\ f_{12} \\ f_{13} \\ f_{21} \\ f_{22} \\ f_{23} \\ f_{31} \\ f_{32} \\ f_{33} \end{bmatrix} = 0$$

~10000 ~10000 ~100 ~10000 ~10000 ~100 ~100 ~100 1

Orders of magnitude difference between column of data matrix

→ least-squares yields poor results

Normalized 8-point algorithm

1. Transform input by $\hat{\mathbf{x}}_i = \mathbf{T}\mathbf{x}_i$, $\hat{\mathbf{x}}_i' = \mathbf{T}\mathbf{x}_i'$
2. Call 8-point on $\hat{\mathbf{x}}_i, \hat{\mathbf{x}}_i'$ to obtain $\hat{\mathbf{F}}$
3. $\mathbf{F} = \mathbf{T}'^{\mathrm{T}}\hat{\mathbf{F}}\mathbf{T}$

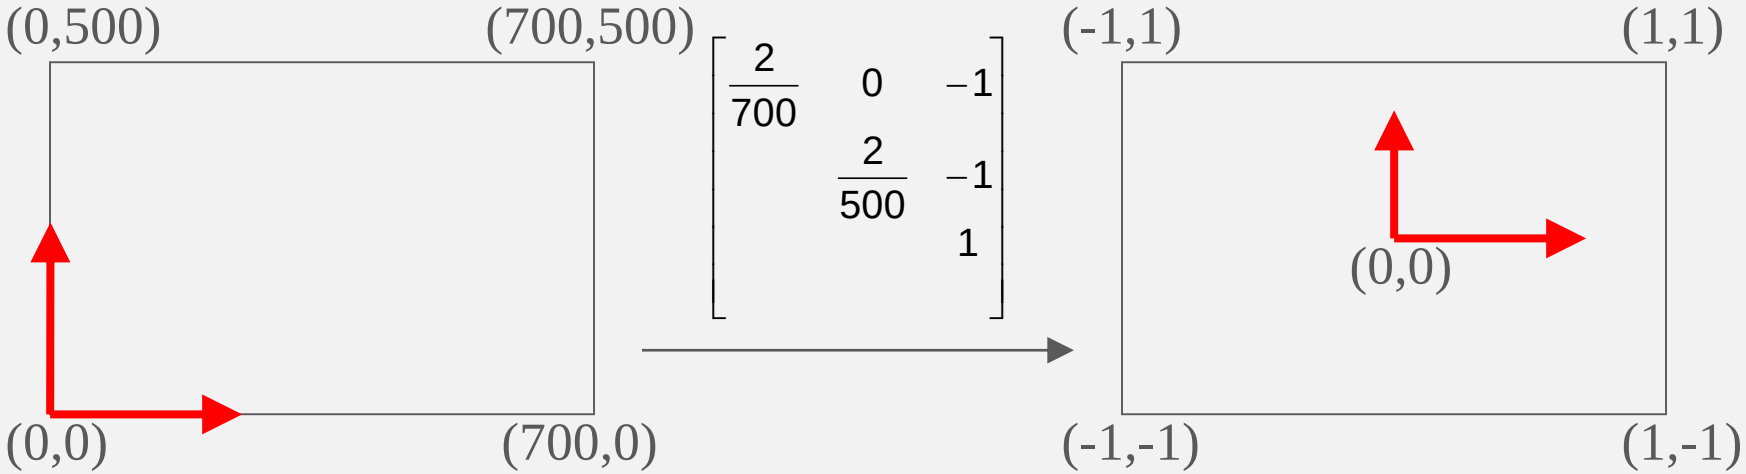
$$\mathbf{x}'^{\mathrm{T}}\mathbf{F}\mathbf{x} = 0$$

$$\hat{\mathbf{x}}'^{\mathrm{T}}\mathbf{T}'^{-\mathrm{T}}\mathbf{F}\mathbf{T}^{-1}\hat{\mathbf{x}} = 0$$

$$\hat{\mathbf{F}}$$

Normalized 8-point algorithm

- Normalized least squares yields good results
- Transform image to ~[-1,1]x[-1,1]



Normalized 8-point algorithm

```
[x1, T1] = normalise2dpts(x1);
[x2, T2] = normalise2dpts(x2);

A = [x2(1,:)‘.*x1(1,:)'   x2(1,:)'.*x1(2,:)'  x2(1,:)' ...
     x2(2,:)'.*x1(1,:)'   x2(2,:)'.*x1(2,:)'  x2(2,:)' ...
     x1(1,:)'             x1(2,:)'            ones(npts,1) ];

[U,D,V] = svd(A);

F = reshape(V(:,9),3,3)';

[U,D,V] = svd(F);

F = U*diag([D(1,1) D(2,2) 0])*V';

% Denormalise
   F = T2'*F*T1;
```

Normalization

```
function [newpts, T] = normalise2dpts(pts)

    c = mean(pts(1:2,:)')';    % Centroid
    newp(1,:) = pts(1,:)-c(1); % Shift origin to centroid.
    newp(2,:) = pts(2,:)-c(2);

    meandist = mean(sqrt(newp(1,:).^2 + newp(2,:).^2));
    scale = sqrt(2)/meandist;

    T = [scale     0    -scale*c(1)
           0     scale  -scale*c(2)
           0       0          1      ];
    newpts = T*pts;
```

RANSAC

repeat

- select minimal sample (8 matches)

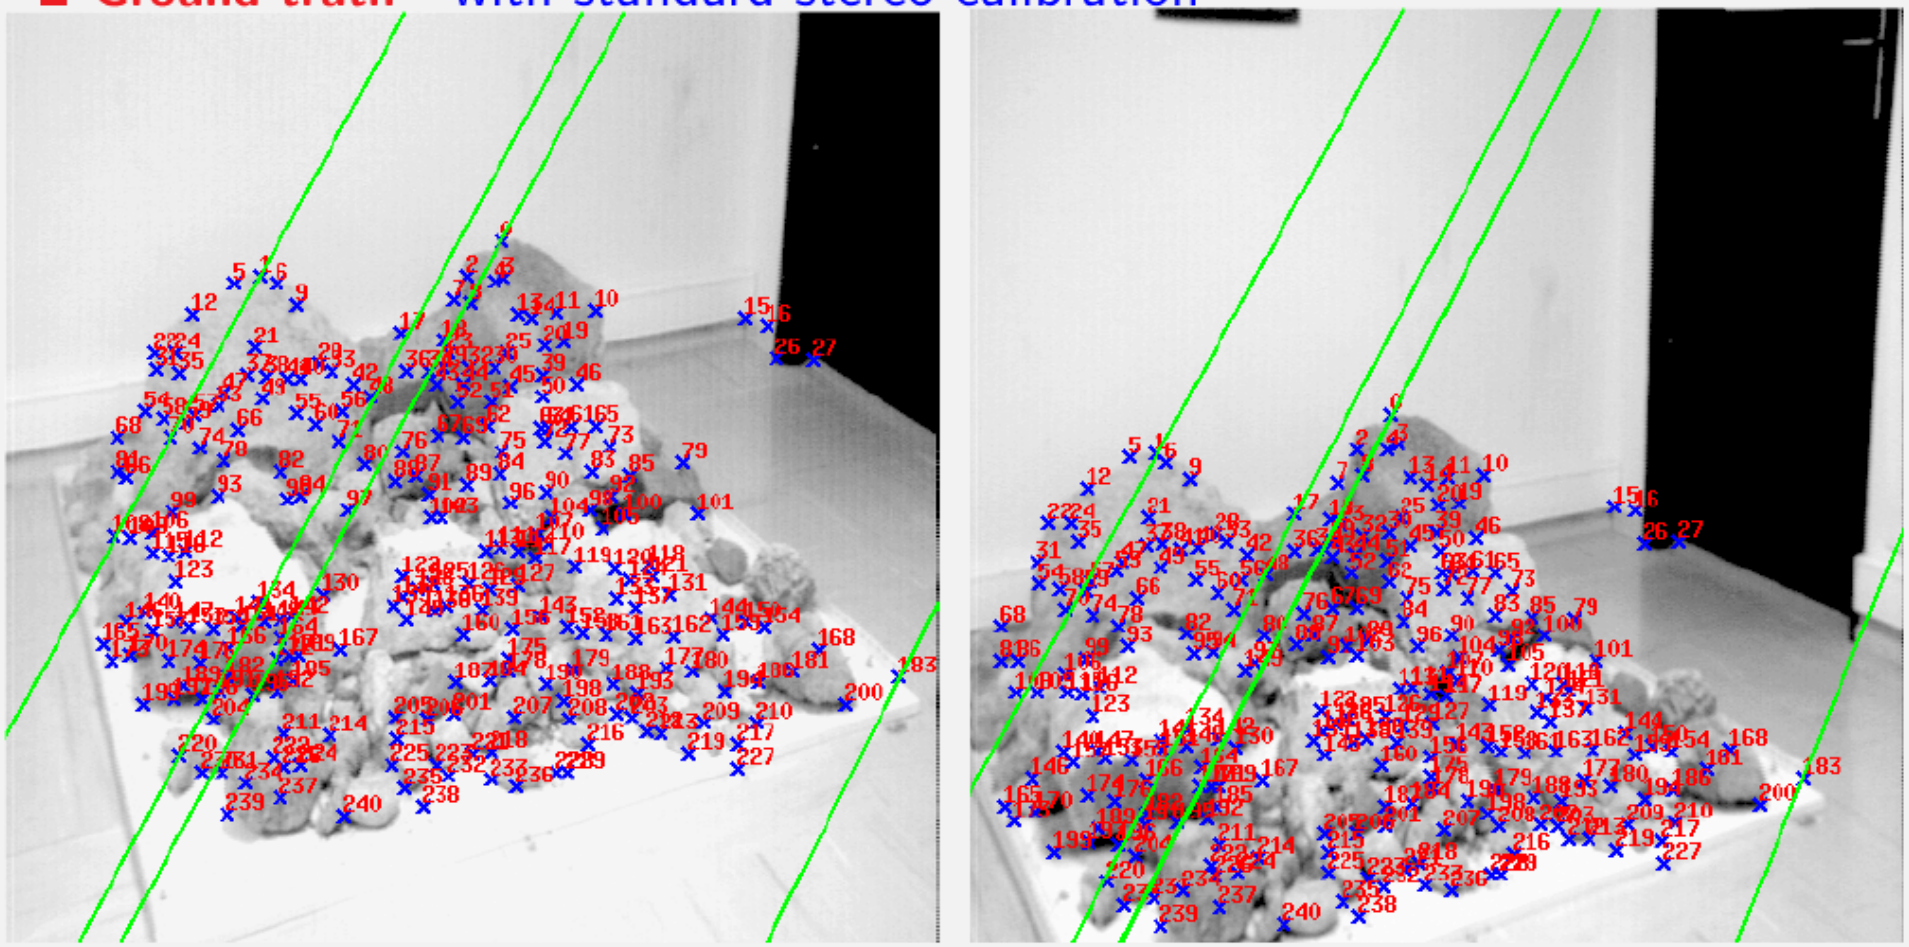
- determine inliers

until $\Gamma(\#inliers, \#samples) > 95\%$ or too many times

compute F based on all inliers

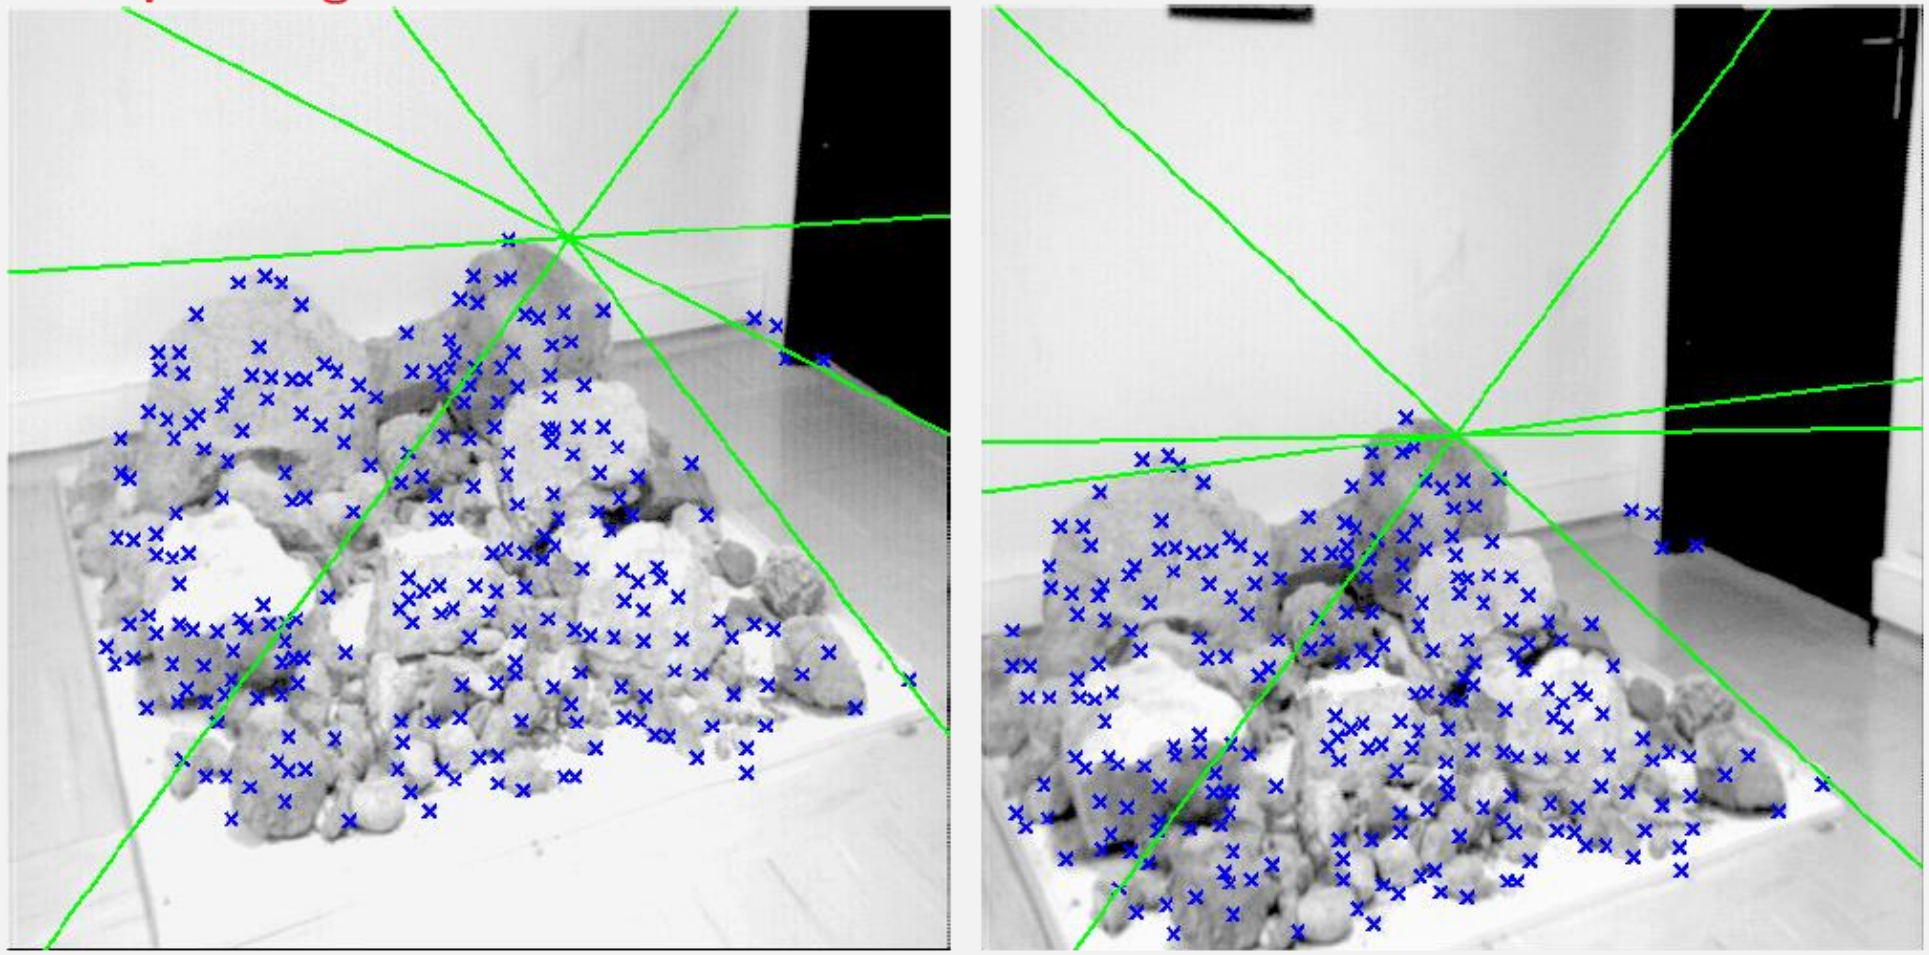
Results (ground truth)

- **Ground truth** with standard stereo calibration



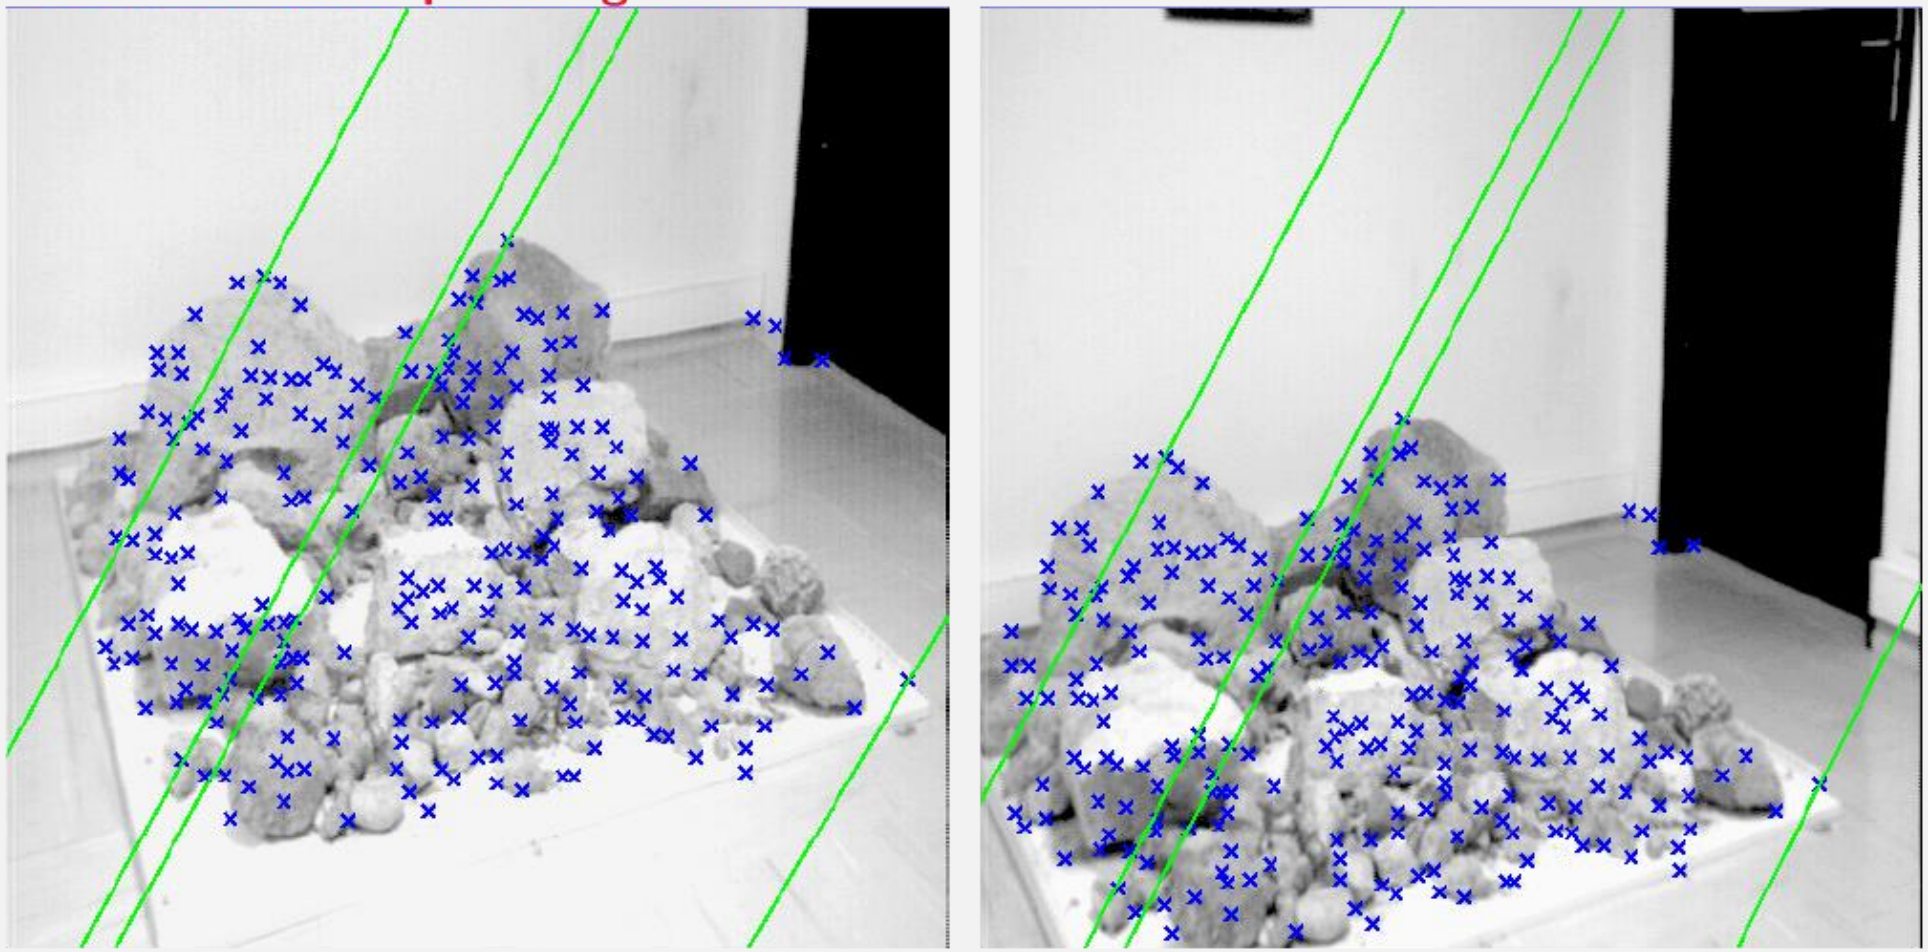
Results (8-point algorithm)

- 8-point algorithm

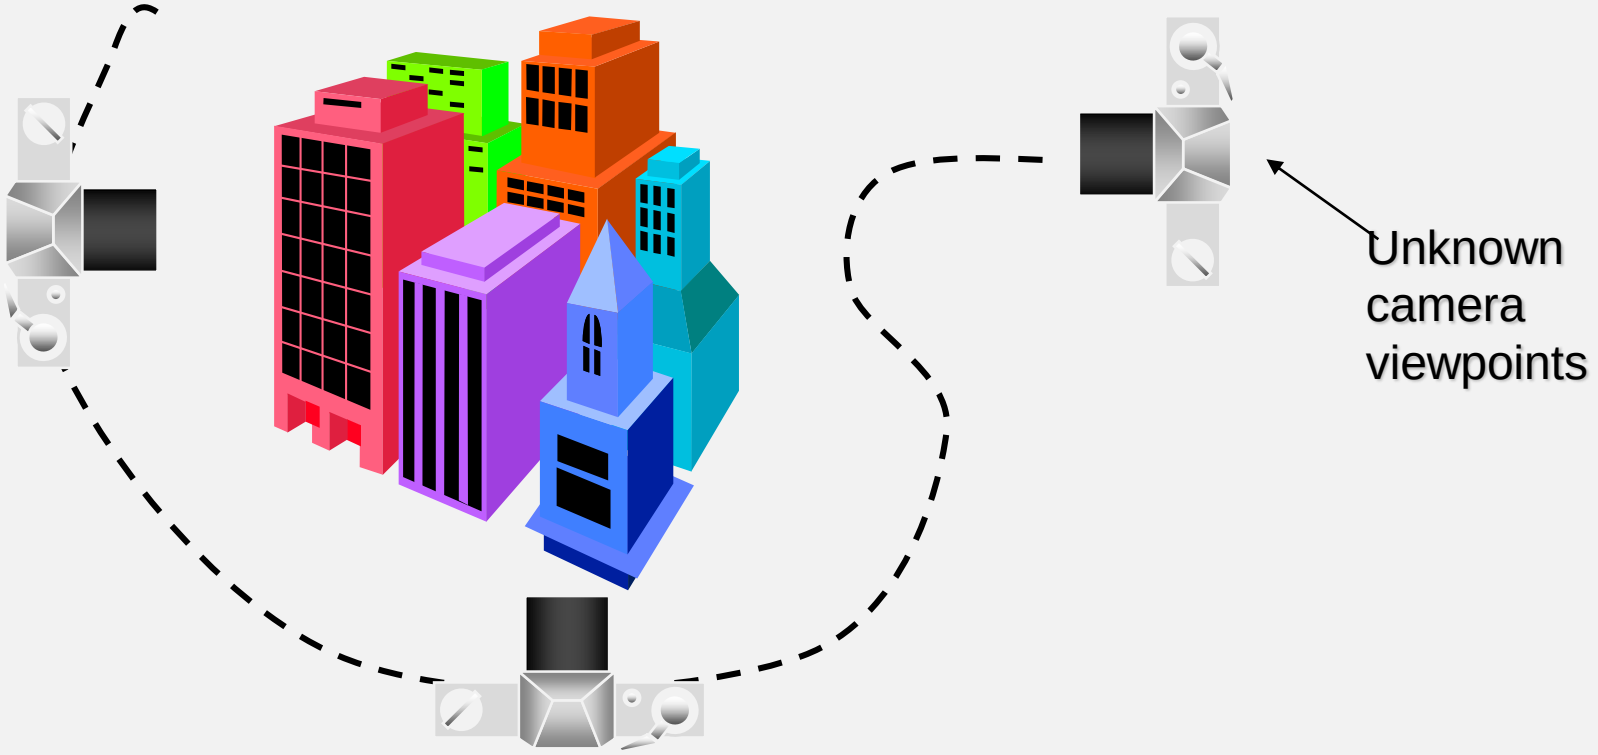


Results (normalized 8-point algorithm)

- Normalized 8-point algorithm

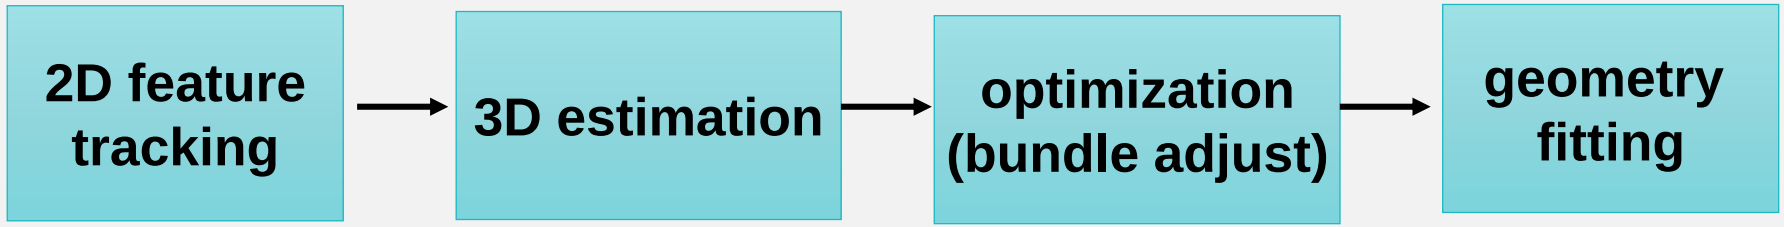


Structure from Motion

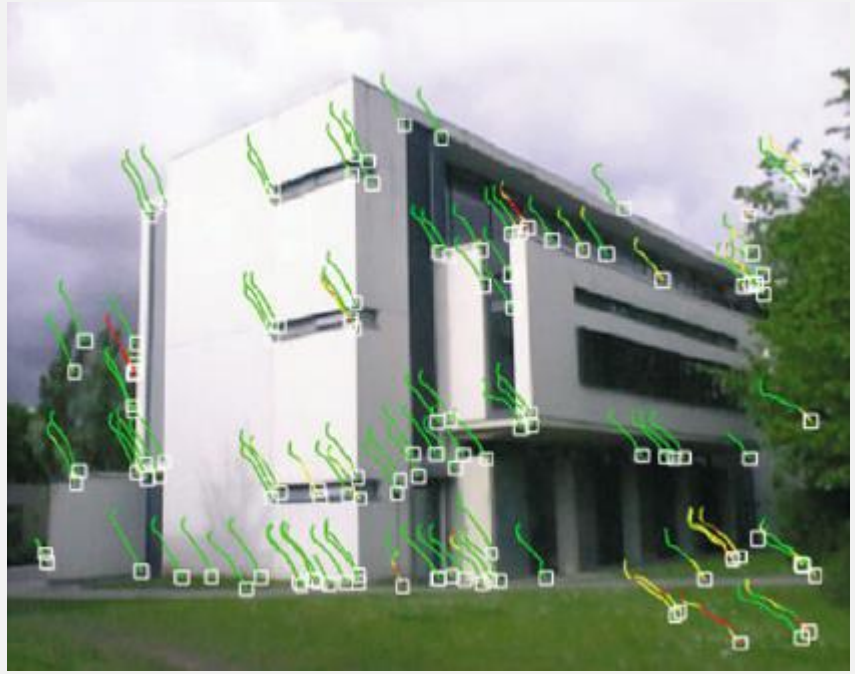


- structure from motion: automatic recovery of **camera motion** and **scene structure** from two or more images.
- It is a self calibration technique and called *automatic camera tracking* or *matching move* **or** *SLAM*.

SFM Pipeline



- Step 1: Track Features
  - Detect good features, Shi & Tomasi, SIFT
  - Find correspondences between frames
    - Lucas & Kanade-style motion estimation
    - window-based correlation
    - SIFT matching

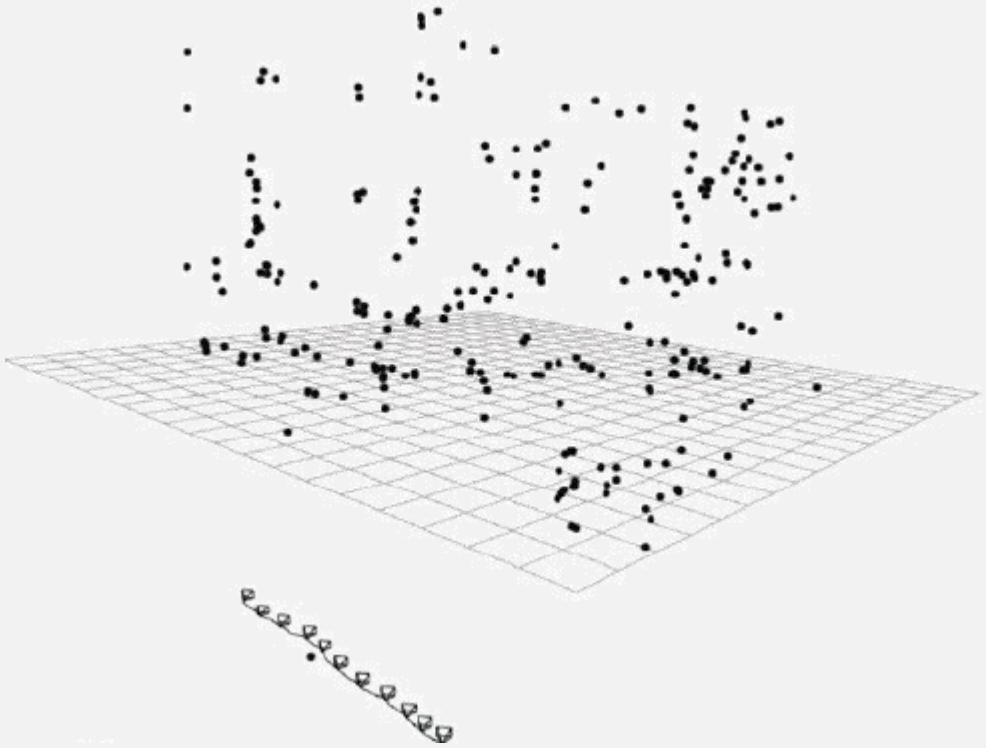


SFM Pipeline

- Step 2: Estimate Motion and Structure
  - Simplified projection model, e.g., **[Tomasi 92]**
  - 2 or 3 views at a time **[Hartley 00]**

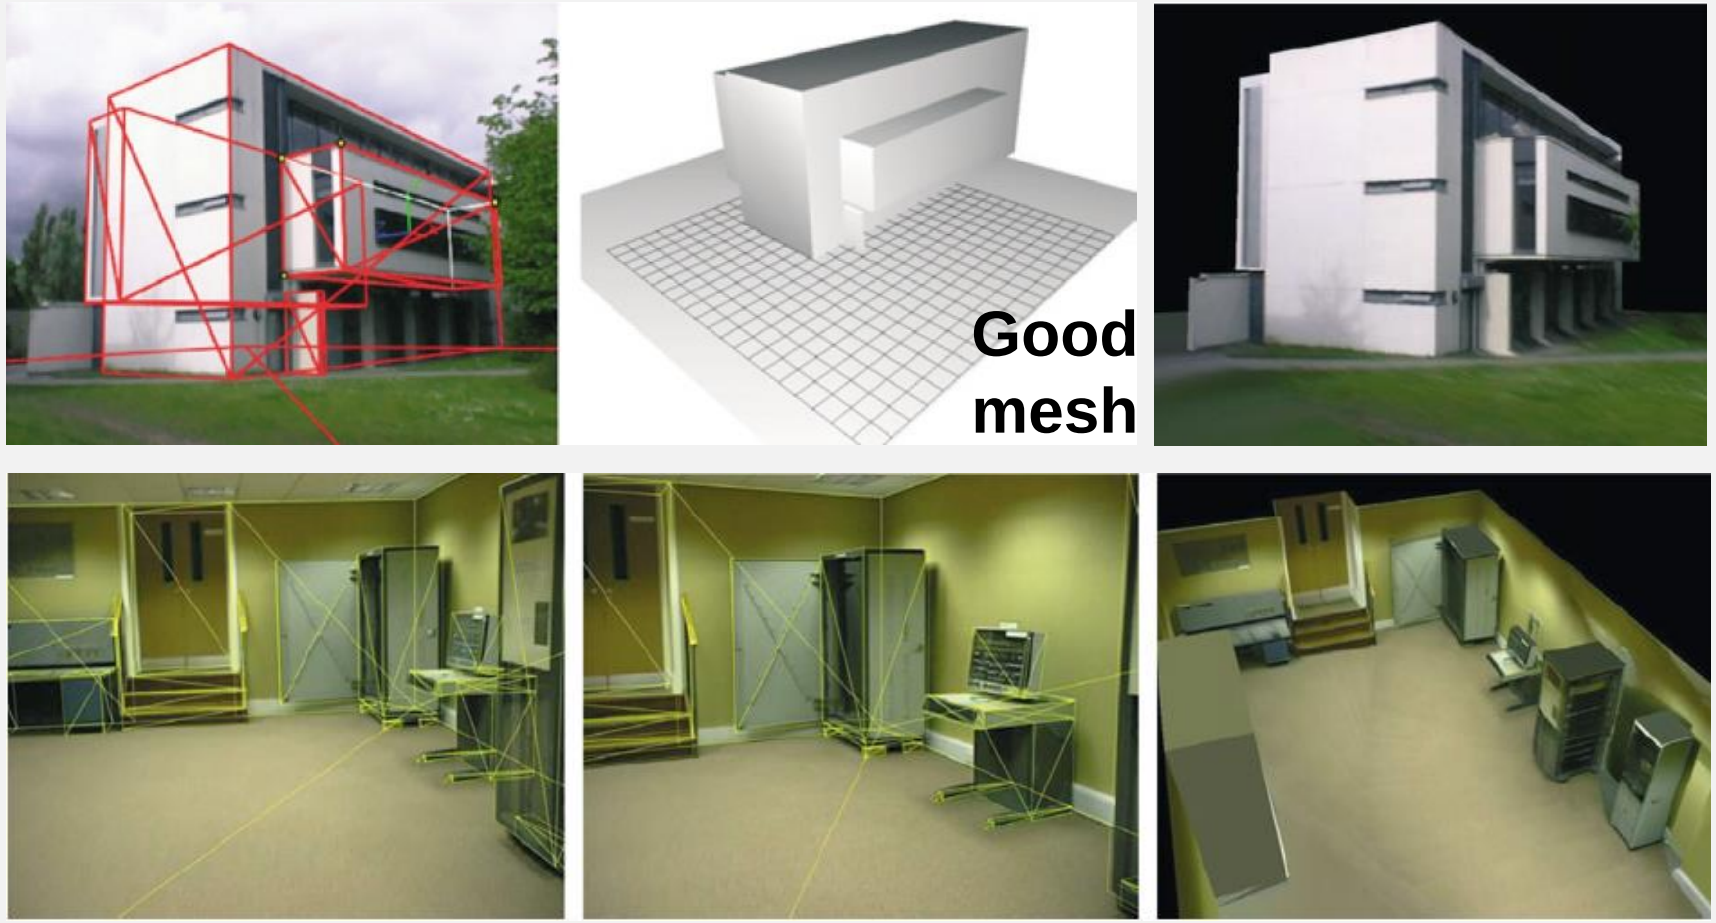
SFM Pipeline

- Step 3: Refine estimates
  - “Bundle adjustment” in photogrammetry
  - Other iterative methods



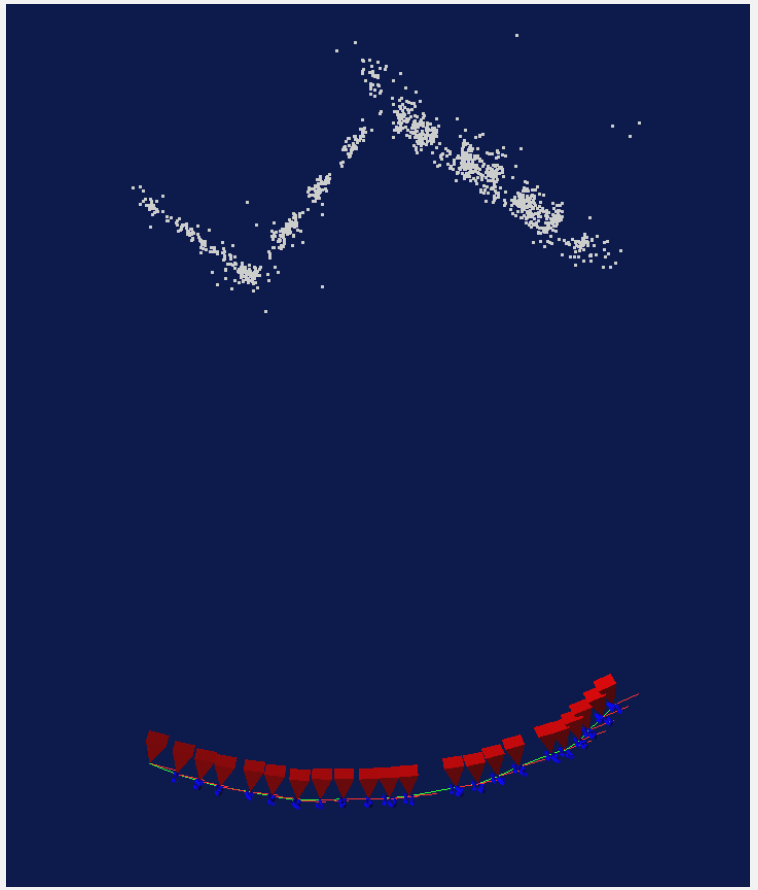
SFM Pipeline

- Step 4: Recover surfaces (image-based triangulation, silhouettes, stereo…)



Factorization Methods (for Initial Guess)

- Problem statement



Notations

- n 3D points are seen in m views
- $\mathbf{q}=(u,v,1)$: *2D image point*
- $\mathbf{p}=(x,y,z,1)$: *3D scene point*
- Π: projection matrix (camera parameters)
- π: projection function
- q_{ij} is the projection of the i-th point on image j
- λ_{ij} projective depth of q_{ij}

$$\mathbf{q}_{ij} = \pi(\Pi_j \mathbf{p}_i)$$

$$\pi(x, y, z) = (x / z, y / z)$$

$$\lambda_{ij} = z$$

Structure from Motion

- Estimate $\prod_j$ and $\mathbf{p}_i$ to minimize

$$\varepsilon(\mathbf{\Pi}_1,\cdots,\mathbf{\Pi}_m,\mathbf{p}_1,\cdots,\mathbf{p}_n)=\sum_{j=1}^{m}\sum_{i=1}^{n} w_{ij}\log P(\pi(\mathbf{\Pi}_j\mathbf{p}_i);\mathbf{q}_{ij})$$

$$w_{ij}=\begin{cases}1 & \text{if } p_i \text{ is visible in view j}\\ 0 & \text{otherwise}\end{cases}$$

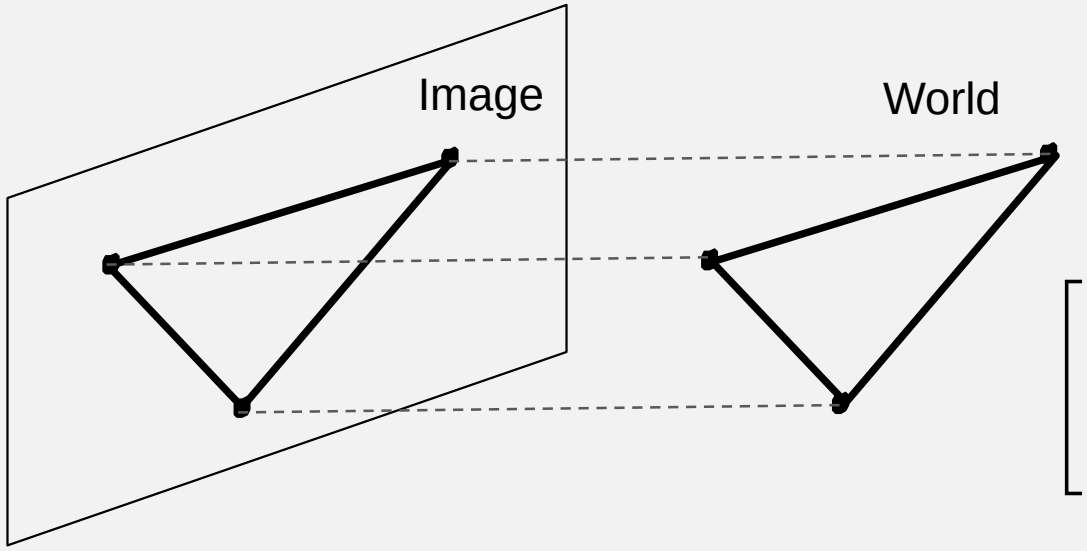
- Assume isotropic Gaussian noise, it is reduced to

$$\varepsilon(\mathbf{\Pi}_1,\cdots,\mathbf{\Pi}_m,\mathbf{p}_1,\cdots,\mathbf{p}_n)=\sum_{j=1}^{m}\sum_{i=1}^{n} w_{ij}\left\|\pi(\mathbf{\Pi}_j\mathbf{p}_i)-\mathbf{q}_{ij}\right\|^2$$

- Start from a simpler projection model

Orthographic Projection

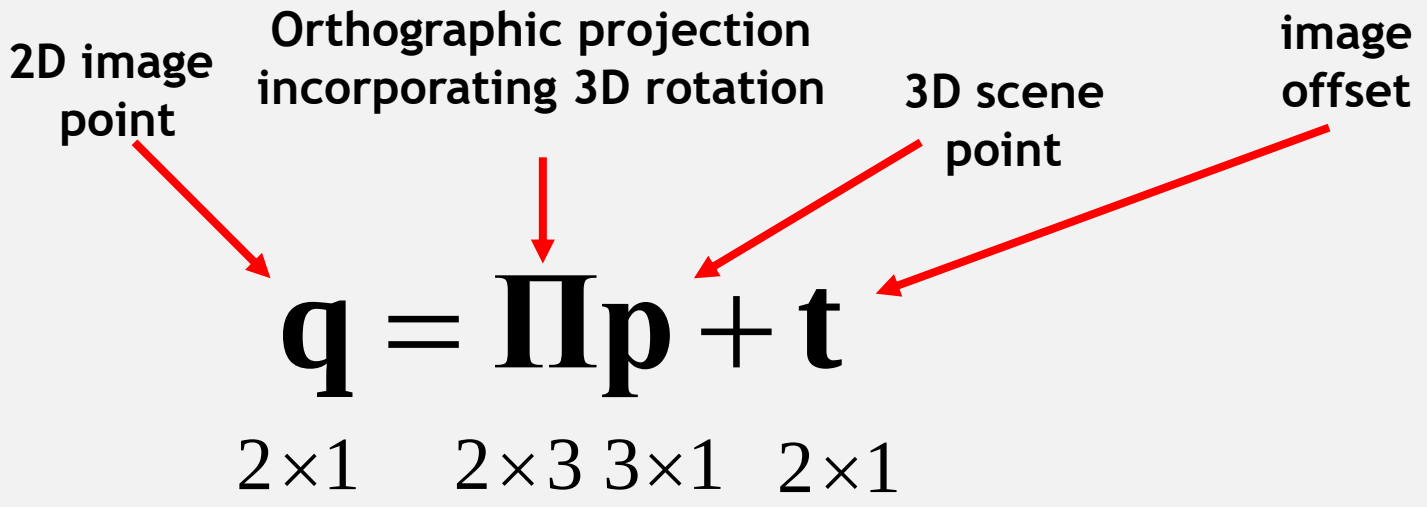
- Special case of perspective projection
  - Distance from the COP to the PP is infinite



$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} \Rightarrow (x, y)$$

  - Also called “parallel projection”: (x, y, z) → (x, y)

SFM Under Orthographic Projection



- Trick
  - Choose scene origin to be centroid of 3D points
  - Choose image origins to be centroid of 2D points
  - Allows us to drop the camera translation:

$$\mathbf{q} = \Pi\mathbf{p}$$

Factorization (Tomasi & Kanade)

projection of *n* features in one image:

$$\underset{2\times n}{\begin{bmatrix}\mathbf{q}_1 & \mathbf{q}_2 & \cdots & \mathbf{q}_n\end{bmatrix}} = \underset{2\times 3}{\prod} \underset{3\times n}{\begin{bmatrix}\mathbf{p}_1 & \mathbf{p}_2 & \cdots & \mathbf{p}_n\end{bmatrix}}$$

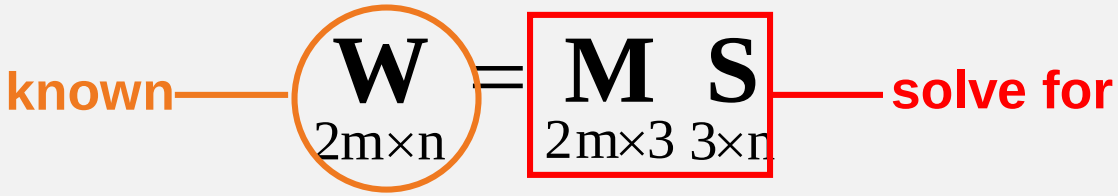
projection of *n* features in *m* images

$$\underset{2m\times n}{\begin{bmatrix}\mathbf{q}_{11} & \mathbf{q}_{12} & \cdots & \mathbf{q}_{1n} \\ \mathbf{q}_{21} & \mathbf{q}_{22} & \cdots & \mathbf{q}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{q}_{m1} & \mathbf{q}_{m2} & \cdots & \mathbf{q}_{mn}\end{bmatrix}} = \underset{2m\times 3}{\begin{bmatrix}\mathbf{\Pi}_1 \\ \mathbf{\Pi}_2 \\ \vdots \\ \mathbf{\Pi}_m\end{bmatrix}} \underset{3\times n}{\begin{bmatrix}\mathbf{p}_1 & \mathbf{p}_2 & \cdots & \mathbf{p}_n\end{bmatrix}}$$

Key Observation: *rank*(**W**) <= 3

W measurement **M** motion **S** shape

Factorization



- Factorization Technique
  - W is at most rank 3 (assuming no noise)
  - We can use singular value decomposition to factor W:

$$\underset{2m\times n}{\mathbf{W}} = \underset{2m\times 3}{\mathbf{M}'}\ \underset{3\times n}{\mathbf{S}'}$$

  - S′ differs from S by a linear transformation A:

$$\mathbf{W} = \mathbf{M}'\mathbf{S}' = (\mathbf{M}\mathbf{A}^{-1})(\mathbf{A}\mathbf{S})$$

  - Solve for A by enforcing metric constraints on M

Metric Constraints

- Orthographic Camera
  - Rows of Π are orthonormal: $\Pi\Pi^T = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$
- Enforcing "Metric" Constraints
  - Compute $\mathbf{A}$ such that rows of $\mathbf{M}$ have these properties

$$\mathbf{M}'\mathbf{A} = \mathbf{M}$$

Trick (not in original Tomasi/Kanade paper, but in followup work)

- Constraints are linear in $\mathbf{A}\mathbf{A}^T$:

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \Pi\Pi^T = \Pi'\mathbf{A}(\mathbf{A}\Pi')^T = \Pi'\mathbf{G}\Pi'^T \qquad \textit{where } \mathbf{G} = \mathbf{A}\mathbf{A}^T$$

- Solve for **G** first by writing equations for every Π_i in **M**
- Then $\mathbf{G} = \mathbf{A}\mathbf{A}^T$ by SVD (since $\mathbf{U} = \mathbf{V}$)

Factorization with Noisy Data

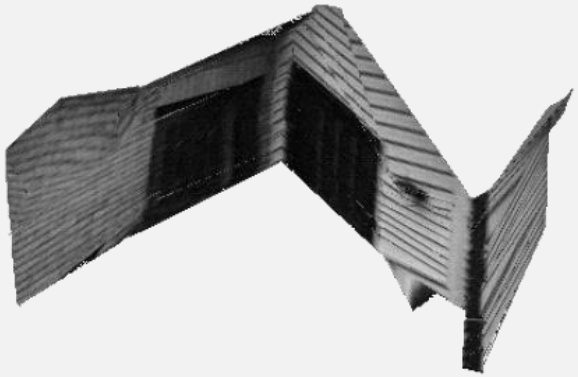
$$\underset{2m\times n}{\mathbf{W}} = \underset{2m\times 3}{\mathbf{M}}\ \underset{3\times n}{\mathbf{S}} + \underset{2m\times n}{\mathbf{E}}$$

- SVD gives this solution
  - Provides optimal rank 3 approximation W′ of W

$$\underset{2m\times n}{\mathbf{W}} = \underset{2m\times n}{\mathbf{W}'} + \underset{2m\times n}{\mathbf{E}}$$

- Approach
  - Estimate W′, then use noise-free factorization of W′ as before
  - Result minimizes the SSD between positions of image features and projection of the reconstruction

Results



Extensions to Factorization Methods

- Projective projection
- With missing data
- Projective projection with missing data

Bundle adjustment

Levenberg-Marquardt Method

- LM can be thought of as a combination of steepest descent and the Newton method.
- When the current solution is far from the correct one, the algorithm behaves like a steepest descent method: slow, but guaranteed to converge.
- When the current solution is close to the correct solution, it becomes a Newton's method.

Nonlinear Least Square

Given a set of measurements $\mathbf{x}$, try to find the best parameter vector $\mathbf{p}$ so that the squared distance $\varepsilon^T \varepsilon$ is minimal. Here, $\varepsilon = \mathbf{x} - \hat{\mathbf{x}}$, with $\hat{\mathbf{x}} = f(\mathbf{p})$.

Levenberg-Marquardt Method

For a small $||\delta_{\mathbf{p}}||$, $f(\mathbf{p}+\delta_{\mathbf{p}}) \approx f(\mathbf{p}) + \mathbf{J}\delta_{\mathbf{p}}$

$\mathbf{J}$ is the Jacobian matrix $\frac{\partial f(\mathbf{p})}{\partial \mathbf{p}}$

it is required to find the $\delta_{\mathbf{p}}$ that minimizes the quantity

$$||\mathbf{x} - f(\mathbf{p}+\delta_{\mathbf{p}})|| \approx ||\mathbf{x} - f(\mathbf{p}) - \mathbf{J}\delta_{\mathbf{p}}|| = ||\epsilon - \mathbf{J}\delta_{\mathbf{p}}||$$

$$\mathbf{J}^T\mathbf{J}\delta_{\mathbf{p}} = \mathbf{J}^T\epsilon$$

$$\mathbf{N}\delta_{\mathbf{p}} = \mathbf{J}^T\epsilon$$

$$\mathbf{N}_{ii} = \mu + \left[\mathbf{J}^T\mathbf{J}\right]_{ii}$$

damping term

Levenberg-Marquardt Method

- $\mu=0 \rightarrow$ Newton's method
- $\mu \rightarrow \infty \rightarrow$ steepest descent method
- Strategy for choosing μ
  - Start with some small μ
  - If error is not reduced, keep trying larger μ until it does
  - If error is reduced, accept it and reduce μ for the next iteration

Bundle Adjustment

- Bundle adjustment (BA) is a technique for simultaneously refining the 3D structure and camera parameters
- It is capable of obtaining an optimal reconstruction under certain assumptions on image error models. For zero-mean Gaussian image errors, BA is the maximum likelihood estimator.

Bundle Adjustment

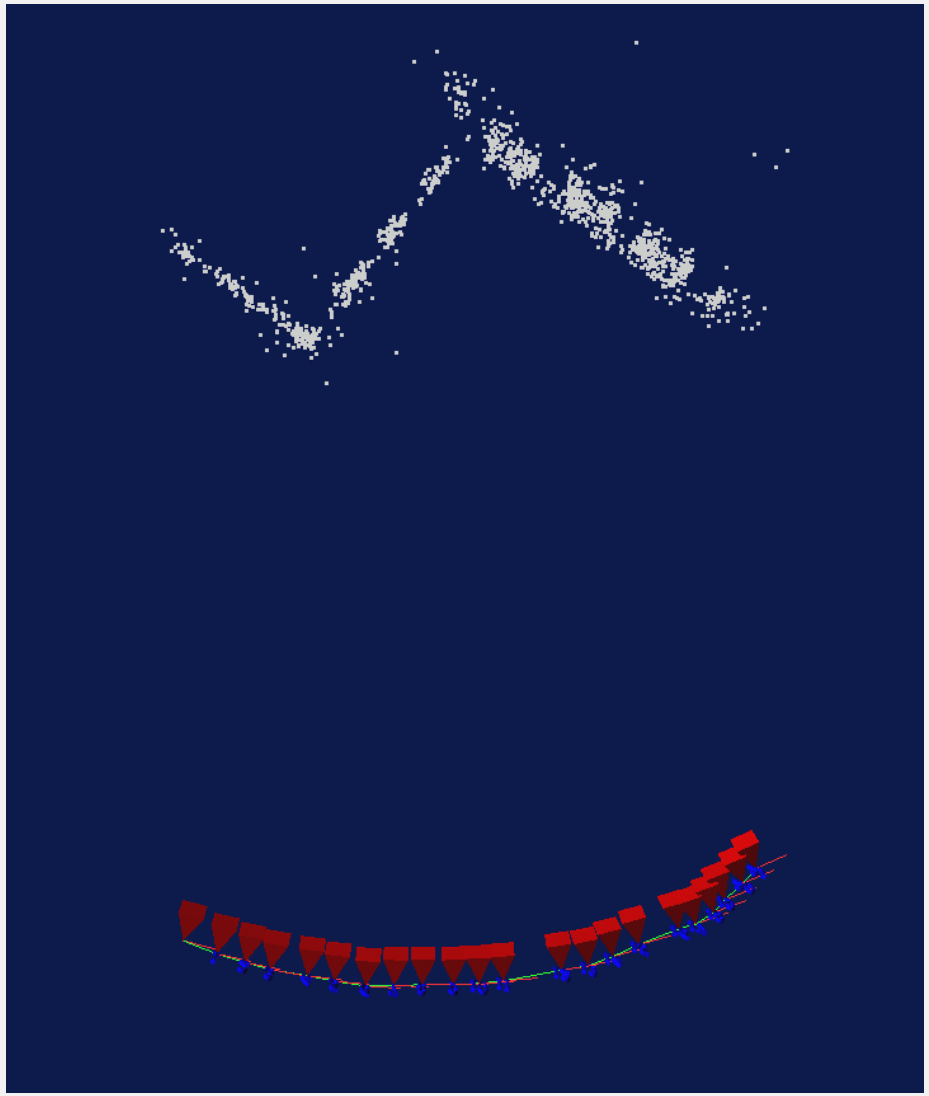
- n 3D points are seen in m views
- x_{ij} is the projection of the i-th point on image j
- a_j is the parameters for the j-th camera
- b_i is the parameters for the i-th point
- BA attempts to minimize the projection error

$$\min_{\mathbf{a}_j, \mathbf{b}_i} \sum_{i=1}^{n} \sum_{j=1}^{m} d(\mathbf{Q}(\mathbf{a}_j, \mathbf{b}_i),\ \mathbf{x}_{ij})^2$$

predicted projection

Euclidean distance

Bundle Adjustment



Bundle Adjustment

3 views and 4 points $\mathbf{P} = (\mathbf{a}_1^T, \mathbf{a}_2^T, \mathbf{a}_3^T, \mathbf{b}_1^T, \mathbf{b}_2^T, \mathbf{b}_3^T, \mathbf{b}_4^T)^T$

$$\mathbf{X} = (\mathbf{x}_{11}^T, \mathbf{x}_{12}^T, \mathbf{x}_{13}^T, \mathbf{x}_{21}^T, \mathbf{x}_{22}^T, \mathbf{x}_{23}^T, \mathbf{x}_{31}^T, \mathbf{x}_{32}^T, \mathbf{x}_{33}^T, \mathbf{x}_{41}^T, \mathbf{x}_{42}^T, \mathbf{x}_{43}^T)^T$$
